The OFFICIAL RECEIVER said, as a matter of fact, there was no case in existence, but there was merely a consultation. Counsel was of opinion that the Articles of Association enabled the Directors to form a reserve fund to such an extent as they thought fit, but that such reserve fund should be to provide for future and not for past losses or depreciations. The sum of £35,000 paid by the Kensington Stores was a premium on the lease, without which the rent would have been much greater, and counsel thought this might properly be placed to the profits of the year. He (the Official Receiver) suggested that, although the amount might be included in profits for the year, the

Digitized by Google

proper course would have been, as the property was depreciated by the surrendering of a valuable frontage, not to allow the assets to remain at the same figure as previously, £47,000 on account of the Cadby Hall premises.

WITNESS said a new source of income was created by the rental, which was an extraordinary piece of profit for the United Company. He thought it might be said that Mr. Rawson was in favour of the profits being valued at the sums given, whilst witness would have preferred to see them put at a lower figure. Mr. Rawson was entitled to a portion of the profits after 15 per cent. had been paid. Witness wrote to the secretary of the United Company upon learning that an interim dividend had been paid at the rate of 15 per cent., saying that it was unusual for an exceptional dividend of that character to be paid before the accounts were made up and certified by the auditors; but as it had been done the responsibility rested solely upon the Directors, and he could only protest against the course which had been adopted. Witness did not see a prospectus issued at about that period inviting further capital, and stating that an interim dividend of 15 per cent. had been paid, and that the Company was being worked very successfully. He remembered objecting once or twice to his name being put upon these prospectuses. He was persuaded to withdraw his objections to the profits made being set forth as the usual profits of an engineering and trading concern; but he did not now think he was wise in allowing himself to be so persuaded. He was not aware that it was intended to repay the £75,000, held as a guarantee, to the liquidators of Woodhouse and Rawson (Limited); he was not consulted as to the expediency of that course. Coming to the year 1891, the gross profits were given as £74,563. There were several exceptional items of profit again in that year, whilst there was a considerable loss on the industrial business—£8,000 on the Kidsgrove Works alone. There was an item of £14,975 entered as Phœnix Trust profits. He heard afterwards, but did not know at the time, that this was a company founded by Baron Grant and Mr. F. L. Rawson. In that year he wrote to Mr. Rawson, pointing out unsatisfactory features in the accounts, suggesting a rearrangement of the same, and stating that as they stood it would be impossible to certify them without appending a very long explanatory statement. Mr. Rawson replied at some length with regard to these matters, and there were also numerous interviews. Eventually a certificate was drafted, stating that the profits arose almost entirely from financial and not from commercial operations, that investments to the extent of £118,000 were exclusively in shares of allied companies, and suggesting that as the guarantee had been renounced no dividends should be paid until those shares had been realised. That certificate was not appended to the balance-sheet, because it was represented to him that it would damage the Company. That statement would have made the shareholders aware of the real state of affairs. He agreed that the fact that the publication of that statement might affect the financial operations of the Company, or the market value of the shares, would not be a sufficient reason for the withholding of the statement. It was true that the commercial operations of the Company were on a comparatively small scale, and they could not very well be put into a much worse condition. He had stated that he should append the statement to his certificate unless certain pledges were given him by the Directors; but he could not recollect that he did receive any such pledges. He attended a meeting of the Board, there was a long discussion, and he was persuaded to withhold the special report referred to. A letter was written to his firm by the Secretary of the Company, undertaking, on behalf of the Company, that the sum owing by Mr. Rawson should be paid by July 31st, and that appeared to be the only pledge in writing which he received. One cause of complaint was that some of the accounts were made up to the end of May only, whilst others were extended to July 31st. It was true that if the accounts of the financial business had not been extended to July 31st, £35,000 profit through the promotion of the Epstein Company would not have been included. Had he known that several of the patents would expire in the course of a year or so he would have required a much larger sum to be written off than was done. He did not think, however, that anything should be written off goodwill. Where a business was worked at a small profit, or none at all, or even at a loss, the amount of goodwill must still remain; but, on the other hand, if the profits were doubled or quadrupled there should be no appreciation of the amount of goodwill. Nearly the only bit of law on the subject of accounts was to the effect that if the capital of shareholders was applied to purchase an asset which had only five years to run, the Directors were entitled to treat as profit and divide as profits any dividend without writing off one penny as depreciation of that asset.

By Mr. MUIR MACKENZIE: Seeing that the £75,000 was left in the hands of Woodhouse and Rawson United as a dividend guarantee fund, the Directors were bound to pay a dividend, even if there had been no profits. It appeared that divergent views were held by the Directors as to what was the proper method of dealing with some of the profits, especially with regard to the profits on the promotion of the Kensington Stores. Lord Aberdare wrote to Sir Rawson Rawson suggesting that certain things should be done, taking practically the same view as witness; but Sir Rawson Rawson gave reasons why the money should be otherwise applied. Lord Aberdare replied that his views were somewhat modified by the further information given, but he still adhered to the principle that the proceeds of the sale to the Kensington Stores should be applied to capital account and not to profits.

By Mr. JENKINS: No shareholder who attended the meetings of the Company could truthfully say he thought the profits arose out of the industrial business. Lord Aberdare and Mr. Pope both clearly stated that a large proportion of the profits arose out of the fourth branch of the Company's business, but no detailed information as to the proportions of profit was given. He had never had the slightest reason to doubt the honesty of any of the statements made to him, and he believed that the Board was composed of honourable men. He had never since seen any reason to change that opinion. What he complained of was that there were certain parts of the accounts which ought to be amplified.

By Mr. F. L. RAWSON: He could not say that it would be fair, profits having been made for the previous year, for the Directors of the Electric Supply Company to declare an interim dividend in 1887 without waiting for the accounts to be made up and audited. He could not say that the loss which eventually resulted in that year was entirely owing to the Edison-Swan action.

The further examination was adjourned until Wednesday of next week.

National Telephone Company v. Morris Bros.

In the Sheffield County Court, last week, before Judge Ellison, a further hearing was given in this action (see *The Electrician*, June 1, page 138), in which the National Telephone Company sued Messrs. Morris Brothers, chemical manufacturers, of Doncaster, whose works are at West Stockwith. The amount claimed was £50 due for rent of a private wire, and the defendants counter-claimed for £50 damages for alleged ineffective service of the telephone wire put up by the Company between their offices at Doncaster and the works at West Stockwith. When the case was previously before the Court it was stated by the defendants that continuous complaints, extending over a period of three years, were made to the Company; and that 119 letters of complaint were written, and constant verbal complaints were made. The Company, on the other hand, submitted that the telephone wire was repaired whenever necessary, and that they were therefore not liable for the damages claimed. The defendant's case on the counter-claim was reached at the first hearing, and now the plaintiff Company presented their case.

Mr. ELLISON, on behalf of the National Company, said that the claim for rent was admitted at the previous hearing, but the defendants claimed damages for breach of agreement. There was an answer on the face of the agreement on which they were suing, even assuming that all the acts alleged by the defendants were true. The first clause of the agreement was to the effect that "the Company shall erect, and (subject to the performance by the lessee of the condition herein contained) maintain in good working order the wire and telephonic apparatus referred to on front hereof." The Company had erected and maintained the wire and apparatus. The third clause was—"The Company shall not be liable for any loss or damage occasioned by the interruption or disturbance of telephonic communication from any cause whatever." The present claim was for interruption or disturbance of telephonic communication. Clause 2 provided that, "In the event of the said wire or apparatus not being in good working order the Company shall repair and restore the same at its own expense and with all possible despatch; but the Company shall not be held responsible or liable to the lessee, in damages or otherwise howsoever, for any delay, provided it uses every reasonable endeavour to restore the communication as speedily as possible." It was not suggested there had been any delay in restoring the communication when the line became interrupted. Mr. Morris admitted that the moment anything was wrong the Telephone Company did their best to put it in order. Messrs. Morris did not complain of any delay, but they complained that the telephone service was bad, and had to be put right very frequently. It was impossible for a telephone company to carry on its business unless clauses similar to those he had read were inserted in their agreement, and therefore the contention that such clauses were unreasonable was untenable. The line was 22 miles long, and the rent £100 per annum. For this sum the Company had not only to erect but to keep the wire in order. The Company could not guarantee that the line would not break, or would not be short-circuited. Counsel on the other side had referred to two or three letters written at the time the contract was entered into, and which served to suggest the varying of the written contract. These letters could not be used as a contract, because they were not stamped.

Mr. WILKINSON, for the defendants, said they were in the nature of a guarantee prior to the signing of the contract.

Mr. ELLISON, however, contended that the telephone fixed by the Company was perfectly fit for the purposes intended, and was as good an instrument as any of its kind in the country. Mr. Morris pleaded that the Company had given him an inefficient telephone, but he (Mr. Ellison) submitted that, even admitting this allegation, there was a conclusive answer by Clause 7 of the agreement, that "The Company reserve to itself the right to disconnect, without notice and without prejudice to the other clauses of this agreement, any subscriber whose rent is overdue." Mr. Morris had been in arrear with his rent, and it was not until within a few days of the action that he paid a substantial amount. The Company had carried out their part of the contract. As to the correspondence which had passed, he contended that the interruptions which had occurred were such as were necessarily incident to a well-constructed telephone.

Mr. G. F. L. PRESTON, manager of the Sheffield district of the National Telephone Company, said the line in respect of which the action was brought was a properly constructed one. Whenever he was at Doncaster he had invariably tried the line, and found it in good order.

Mr. CHARLES HENRY SIBLEY, local manager at Sheffield, who was also called, was asked by Mr. Wilkinson if he considered a telephone line satisfactory which required a strongly-written complaint to the office at least once a week, and replied that it was not satisfactory if the complaints were justified.

Mr. CHARLES BROWN, electrical engineer to the Metropolitan District Railway, said he had inspected the telephone line in question, and it was well constructed. The "fault" record was an average one.

Linesmen were called with regard to the repairs and inspection of the line, and several attributed the interruptions to corrosion of the wire by chemical fumes from Messrs. Morris's works.

At the conclusion of the plaintiff's case Mr. WILKINSON said he did not for a moment suggest that the interruptions caused by a heavy snowstorm, or anything of that kind, were grounds for damages. With a line

Digitized by Google

22 miles in extent, there would be a good deal of interruption due accident; but the complaints covered a great many more times when no such cause as that he had intimated would account for the interruption. The Telephone Company had undertaken to put up a workable line, and the third condition of the contract, he contended, was limited in its interpretation by the two conditions that went before. In the second condition of the contract the Telephone Company recognised liability under certain circumstances. The whole of the complaints of Messrs. Morris came to this, that for a period of three years the Company never had seriously undertaken to put the line in such a condition as to save them from annoyance and interruption which they certainly ought not to have suffered from.

His Honour reserved judgment.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1894 Edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. This valuable book contains 1,000 closely-printed pages, and several new and useful features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," being four Lectures delivered before the Royal Institution in April-May, 1894, by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is in preparation, and will shortly be published.

"ELECTROMAGNETIC THEORY," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

TENDERS INVITED.—The City of London Electric Lighting Company require tenders for twelve months' supply of coal, equal to from 20,000 to 25,000 tons. Specifications can be obtained of Mr. David Cook, engineer and manager to the Company; and tenders must be in to Mr. J. Cecil Bull, secretary, at the offices of the Company, 1 and 2, Great Winchester-street, E.C., by 4 o'clock of Wednesday, the 27th inst.

——— The Corporation of Edinburgh invite tenders for work in connection with their electric lighting scheme. The contracts for which tenders are now required include the supply of cast-iron road boxes, copper strip connectors, &c., gun metal grip boxes, cable connectors, and cones. Copies of the specifications and drawings can be obtained from Mr. E. W. Monkhouse, the Corporation's resident electrical engineer, at the City Chambers, Edinburgh, from whom also all other information can be obtained, as well as from Prof. A. B. W. Kennedy, 14, Old Queen-street, Westminster, S.W. Tenders have to be sent in to Mr. W. Skinner, W.S., town clerk, the City Chambers, Edinburgh, by Wednesday, July 4th. Some further particulars will be found in our advertisement columns.

TENDERS ACCEPTED.—The Newport County Council have received four tenders for the supply and erection of an overhead travelling crane for the electric lighting station, as follows:—Stothert and Pitt, £350; Isles (Limited), £290; T. Smith, £285; Carrick and Ritchie, £275. £250 was the sum provided in the contract for this crane, and Mr. Hammond, electrical engineer to the Council, recommended that the offer of Mr. T. Smith of Rodley be accepted, and this course was adopted by the Council.

——— The London County Council have accepted tenders for india-rubber goods sent in by the India-rubber, Gutta-percha and Telegraph Works Company (Limited).

TENDERS RECEIVED.—The Electric Lighting Committee of the Coventry Corporation have received seven tenders for the erection of the buildings for the electric lighting station in Sandy-lane, from plans and specifications by Messrs. G. and I. Steane, and the Corporation have accepted the tender of Mr. C. G. Hill, of Coventry, for the sum of £6,829, including extras of £180. This was the lowest tender. A clerk of the works is to be appointed at four guineas a week. The site selected leaves ample room for future extension. An engine and boiler house is included in the buildings to be erected.

POST OFFICE AND THE NATIONAL TELEPHONE COMPANY.—The Postmaster-General in the House of Commons last night said that negotiations were still going on between the Department and the Telephone Company, and the delay in completing was due to the immense amount of detail work involved. He did not think the delay had enabled the Telephone Company to increase their monopoly, or place themselves in a better position than those municipalities which wished to obtain licences. Hon. gentlemen seemed to forget that the National Company only enjoyed a temporary licence terminating in 1911, and every month that passed must have the effect of reducing the value of their property. The agreement which was being negotiated was simply to give effect to the agreement made by the late Government for the purchase of the trunk lines, and did not involve interference with existing licences.

ENGINES FOR SALE.—The Brush Company have two vertical compound non-condensing Goodfellow engines for sale.

SALE OF PLANT.—On Wednesday, the 27th inst., at Douglas (Isle of Man), by order of the official liquidators, Messrs. W. M. Kernish and Jno. J. Taggart, 21, Athol-street, Douglas, a sale will take place of an immense assemblage of valuable and useful effects, which includes gas engines, Davey-Paxman semi-portable tubular boilers, Brush dynamos and arc lamps, vulcanised and braided cable, &c., &c., particulars of which will be found in our advertisement columns.

DISSOLUTION OF PARTNERSHIP.—The firm of Bennett and Co., carrying on business at the Dynamo Works, Park Cross-street, Leeds, as electrical engineers, has been dissolved. The debts will be paid by Mr. R. F. Winder, who carries on the business.

——— We regret that in our issue of the 8th inst. it was announced that Mr. J. L. Fuller would carry on the business of Messrs. Fuller and Tate, at 20, Bucklersbury, E.C., instead of a *similar* business, as announced in his circular.

APPOINTMENT.—Mr. F. L. Todd, of Glasgow, has been appointed to the post of assistant electrical engineer to the Edinburgh Corporation.

APPOINTMENT VACANT.—The Vestry of St. John, Hampstead, are prepared to appoint an electrical engineer to take charge of their electric lighting station, at a salary of £200 per annum. Applications must be sent in to Mr. Arthur P. Johnson, vestry clerk, Vestry Hall, Hampstead, not later than July 2nd. Some further particulars will be found in our advertisement columns.

BANKRUPTCY.—A meeting of the creditors of John Webster and Joseph Hayes, trading as Webster and Co., at Wheat Sheaf Works, Hall Lane, Bradford, electrical engineers, &c., was held at the office of Messrs. Rawnsley and Peacock, Bradford, last week. A statement of affairs was presented showing liabilities £317. 19s. 8d. and net assets £592. 12s. 1d. It was resolved that a deed of assignment be executed in favour of Mr. John Butterfield, C.A., who as trustee will continue the business with a view of ultimately paying 20s. in the pound. A committee of inspection was appointed, consisting of Messrs. Matthews (Messrs. Rosling and Matthews), Schofield, Payn, and Edmondson.

REMOVAL.—Mr. Albion T. Snell, Assoc. M. Inst. C.E., M.I.E.E., has removed from Brightside, Salusbury-road, N.W., to South View, Brondesbury-road, N.W.

——— Messrs. F. A. Robinson and Co., engineers, merchants, and shippers, have removed from 69, Cornhill, to 54, Old Broad-street, E.C.

OIL-TESTING MACHINE.—Mr. H. F. L. Orcutt, from the London office of Messrs. Ludw. Loewe and Co., sends us an illustrated pamphlet relating to a new oil-testing machine brought out by the firm. The object of the machine is to ascertain by mechanical means the lubricating qualities of oil, and to register the same by means of diagrams. The machine covers a floor space of 41in. by 26¾in., and weighs 920lb.; speed 200 revolutions per minute, or as required.

CARRIAGE LIGHTING.—The new system of carriage lighting by electricity recently brought out by the Bristol Electric Safety Lamp Works, of 63, Queen Victoria-street, can be seen at work at the Coaching Exhibition now being held at the Royal Aquarium, Westminster, S.W., where a drag built by Messrs. Holland and Holland is lighted electrically.

MINERS' LAMPS.—A number of electric lamps made by the Bristol Company have, it is stated, been used with success by the rescuing parties in the great mining disaster at Karwin (Austria).

THE ROYAL ALFRED AGED MERCHANT SEAMEN'S INSTITUTION.—This is a charity with which in the past many telegraph men have been closely associated, and even at the present time considerable aid is rendered by the leading telegraph and cable manufacturing companies. Owing to the recent deaths of several gentlemen who have taken great interest in the Institution, and have been the means of providing considerable funds, it seems likely that telegraph men may overlook the claims of an Institution which does not make so prominent a show as many other charities, but which none the less deserves the cordial support of the telegraphic and general public. At the annual festival held at the Hôtel Métropole on Wednesday last, the Chairman pointed out the claims which the Institution undoubtedly possesses on the support of everyone concerned in our merchant shipping, and regretted to announce that, owing to the reduced condition of the Society's funds, nothing approaching justice could be done to the numerous applicants for the benefits offered by the charity. No less than 250 names are now on the list, and for only about 20 of these can provision be made. An earnest appeal was made for funds in support of a most deserving body of old men. Many gentlemen well known in the electrical world were present at the festival, with which the late Sir James Anderson, Sir George Elliot, and Capt. Halpin were closely identified.

Digitized by Google

Cooking by Electricity.—On Friday last the Directors of the City of London Electric Lighting Company invited a number of gentlemen to the Cannon-street Hotel, E.C., to witness the cooking, and to join in the first public dinner cooked throughout by electricity within the Company's supply district. A large gathering supported Sir David Salomons, who presided, the guests including the Lord Mayor, Prof. S. P. Thompson, Mr. W. H. Preece, C.B., Mr. C. Braithwaite, Prof. J. A. Fleming, Dr. Ernest Hart, Col. Martindale, Sir Myles Fenton, Sir Henry Oakley, Mr. Emile Garcke, Mr. David Cook, and Mr. J. Cecil Bull. The Company having done justice to the menu, which was voted a great success, the Chairman, in proposing the toast, "Success to the Development of Electricity," said the City of London Company had become pioneers in a new development of the application of electricity to cooking purposes, and had practically demonstrated its utility by the dinner given that evening. The food those present had eaten was unadulterated by carbonic acid, carbonic oxide gas, or sulphuretted hydrogen. It was distinctly noticeable that the viands they had partaken of were absolutely devoid of any flavour other than that properly appertaining to them, and when, in addition to this most important quality, it was pointed out that the Company had decided to charge only half rates (4d. per unit) for current supplied for cooking and heating purposes, he felt quite sure that in the busy City of London a considerable demand would be created for a method of cooking which, in addition to the advantages pointed out, took up little room, made absolutely no unpleasant smell, and was cleanly to the last degree. The number of ovens, hot-plates, and other apparatus used provided for 120 guests, the number of electrical units used being 60, which gave a cost of 2d per head. This was a result which could not be considered otherwise than as eminently satisfactory to all concerned, and the catering section of the public would, he felt sure, not be slow in adopting this simple and effective means of overcoming all the difficulties of the bad old systems. The field for the electrical system of cooking and heating was a large one, and promised to become an important adjunct to the Company's lighting operations. The greater portion of the apparatus used for cooking the dinner including six large ovens, sauce and frying-pans, was supplied by Messrs. Crompton and Co., of 148, Brompton-road, S.W., the General Electric Company, of Queen Victoria-street, supplying the remainder.

Aberdeen.—The Watch Committee of the Town Council have decided to recommend the adoption of a proposal to light the new police barracks and prison buildings throughout by electricity.

Bank Lighting.—Messrs. Drake and Gorham have secured an order to instal the electric light at the Consolidated Bank, Manchester. About 80 16 c.p. lights will be required, the current being obtained from the Corporation's supply.

Basingstoke.—Mr. Robert Hammond is preparing a report for the Town Council on the electric lighting question at a fee of 25 guineas. An amendment that tenders be invited for the lighting of the town by electricity, and that liberty be given to the Electric Lighting Committee to employ Mr. Hammond to advise the authority on the matter, was also put and negatived.

Bedford.—At the last meeting of the Town Council the Electric Light Committee recommended that application should be made to the Local Government Board for sanction for borrowing £12,000 to provide funds for the necessary buildings, machinery, and plant for supplying electrical energy within the borough for private and public purposes, in accordance with the plans and estimates prepared by Mr. F. H. Medhurst. Mr. Richards, proposing the adoption of the Committee's recommendation, said that a £12,000 loan for 30 years would be met by a rate of 1d. in the pound for each half-year, which the Committee hoped would be returned from the income derived from the supply of electric light and power in the Council's area. The recommendation was adopted unanimously.

Berlin.—A correspondent describes a carriage used by the Emperor William II. Not only are the interior and exterior lighted by electricity, but the harness is also smothered with small electric lamps, the whole presenting a most original appearance.

Brechin.—The Town Council have decided that the Committee recently appointed by the Police Commission to inquire into the details connected with the introduction of the electric light into the city should also act on behalf of the Council.

Brewery Lighting.—The Burton-on-Trent Brewery, owned by Mr. S. Evershed, M.P., is being fitted throughout with the electric light.

Carlisle.—In a discussion which took place on a report of the Gas Committee of the Town Council, Mr. Saint referred to the interest taken in the electric lighting question by the Mayor, and wished to know whether the subject had received the attention of the Gas Committee. Mr. Forster, Chairman of the Committee, in reply, said that "as the Corporation were in possession of an excellent gas plant the Committee did not think it advisable to enter into any discussion on the electric lighting question." The Mayor subsequently said he had mentioned the subject on two or three occasions, but it had been looked upon with great fear and alarm. He himself had no doubt that, if the Committee had the courage to spend a few thousand pounds, electric lighting would pay much better than the gas works; but against the electric light there was prejudice, which, at the present moment, it was difficult to overcome.

Church and Chapel Lighting.—The electric light is being substituted for gas at the Marylebone Presbyterian Church, Upper George-street, W.

City of London.—The City of London Electric Lighting Company announce that they are now prepared to supply electricity for all purposes in every street and lane within the City of London and in the district of St. Saviour's, Southwark, and offer to consumers who undertake to use 75 per cent. of their current between the hours of 10 p.m. and 6 a.m. the special rate of 4d. per Board of Trade unit, which rate is also now charged at all times of the day or night for current used for heating, cooking, and motive power. The Company have opened show rooms at Queen-street, Cheapside, where appliances for heating and cooking can be purchased or hired and information on the subject obtained.

Canterbury.—The Town Council have received a letter from the County of London and Brush Provincial Company intimating that, provided two gentlemen of good financial position and influence in the district will consent to act as Directors of the Canterbury Company, each investing £500 as Director's qualification, and provided that a sum of not less than £6,000, and not more than £7,500 of the first issue of shares be subscribed locally, the Brush Provincial Company will be prepared to find twice the amount of the local subscription, and to proceed with the work within the present year. After discussion it was decided that the suggestion made by the Company that the Mayor should call a meeting to discuss the question, was agreed upon, and a date will shortly be fixed.

Coventry.—The City Council have received the sanction of the Local Government Board for borrowing £20,000 for electric lighting purposes.

Devon.—At the County Council meeting last week estimates were discussed for improving the water supply and for lighting the Devon County Asylum by electricity. The Finance Committee recommend that the amounts required for carrying out the works should be raised by loan, and application is to be made to the Local Government Board for consent to the borrowing of £8,000 for these purposes.

Dundee.—Mr. Brownlee, electrical engineer to the Dundee Corporation, has recommended the extension of the electric lighting works by the putting down of a 200-h.p. engine and dynamo set. This will bring the available horse-power up to 860. It is anticipated that a further extension will be required next year.

Edinburgh.—Arrangements have been made for laying the foundation stone of the electric lighting station on Monday next, at four p.m., by the Lord Provost, Sir J. A. Russell. A popular lecture will be given in the Albert Hall by Prof. A. B. W. Kennedy.

Edmonton.—A notice has been received by the Local Board from the Tottenham and Edmonton Electric Light and Power Company notifying their intention to apply to the Board of Trade for power to light a portion of the Edmonton district by electricity, and asking the support of the Board for the application. It was decided that the engineer and secretary to the Company should attend the next meeting of the Board to explain the exact position.

Electric Traction in Russia.—The municipal authorities of Ekaterinodar are inviting tenders until July 25th for the establishment of a system of electric tramways in the town. Ekaterinodar is an important town in the Government of Kouban in South Russia.—The Allgemeine Electricitats Gesellschaft of Berlin about two years ago introduced a system of electric traction on some of the tramway lines in the town of Kiew. This has proved so successful that electricity has just been adopted on three other lines in the town, making now 13 kilometres of electric tramway in Kiew.

Electrically Propelled Vehicles.—Messrs. Taylor, Cooper and Bednell, of Coventry, have completed the construction of a car-wagonette, propelled by electricity, from the designs of Messrs. Blumfield and Garrad. The vehicle has seats for four, and runs on four pneumatic-tyred wheels, with ball bearings. The frame, which is carried on springs, is constructed of weldless steel tubing, similar to that used in the manufacture of cycles. A battery of 24 storage cells is used, and these are placed beneath the two seats and lasts for about seven hours, the motor being fixed beneath the vehicle. The motor is of 1-h.p. nominal, and will give 2-h.p. for a short time in case of necessity. The switch, steering, speed regulation gear, and brake are controlled from the front seat. The car, which is said to attain a speed of from 3½ to 13 miles per hour, can be propelled either backwards or forwards. The manufacture of such vehicles is particularly suited to cycle works, and, if the novelty is favourably received, will find employment for cycle hands during the slack season of the year.

Digitized by Google

FAREHAM.—An adjourned meeting of the Local Board has been held to consider a letter from the Electric Lighting Company on the question of public lighting, to the effect that, unless the Company could obtain a large amount of public and private support they did not feel justified in carrying on the business any longer. The letter suggests that, if the undertaking be abandoned, the Board of Trade would give the Local Board the option of purchasing the plant as it stood; but, as an alternative, asked the Board to put up an additional ten arc lamps at an increased cost of £150 a year. After a long and heated discussion, the offer respecting additional lighting was withdrawn by the Company, on the ground that the shareholders and bondholders could not fairly be asked for more capital to put the electric lighting wires underground. It is satisfactory to learn that the negotiations between the Company and the Local Board are still likely to lead to a satisfactory arrangement, under which the Board will purchase the Company's business. At the meeting on Friday last the Board passed a resolution under which it was decided "to purchase the business of the Company for a sum of not more than £5,000, on condition that the Company undertake to lay underground the portion of the wires so required by the Board of Trade, and to undertake to provide a duplicate engine for a further sum of not exceeding £1,000." A further meeting is to be held at which this decision will be discussed.

FIRE.—A fire which promised to prove of serious dimensions broke out at the South Metropolitan District Schools at Sutton, Surrey, on Sunday last; but the building, which is isolated, is in direct electrical communication with the Sutton Local Board Fire Brigade, the members of which were by this means on the spot promptly after the first outbreak, and saved the building, which would otherwise have been totally destroyed. The schools provide accommodation for 1,700 workhouse children.

GEELONG (AUSTRALIA).—The Town Council of Geelong have agreed that it is desirable to light the town by electricity, and have under consideration a proposal by the Crompton Electric Supply Company to instal the light in the town at an estimated cost of £15,000, with an annual up-keep charge of £1,400.

GLASGOW.—A decision was come to at a meeting of the Watching and Lighting Committee last week by which a proposal to extend the supply of electric light to certain additional streets was negatived on the grounds of the increased cost. It will be remembered that some time back the Glasgow Corporation decided to extend the lighting, and this decision appears to be a departure from the previous resolution of the Council.——A report has been presented to the Corporation, showing the annual expense of the telephones and telephone connections rented by the Corporation, and the several Trusts connected therewith. The total amounts to £497 per annum. The Corporation have agreed to enter into a contract with the National Company to provide telephonic communication between the Water Commissioners' office in John-street, Glasgow, and Strathblane and other positions, at £93 per annum, the offer to take effect upon the expiry of the existing agreements with the Post Office.

HACKNEY (LONDON).—At the last meeting of the Vestry it was agreed that the Special Committee appointed to consider the electric lighting question be requested to bring up a report as to the present position of the Hackney Electric Lighting Order, 1893.

HAMPSTEAD.—The Electric Lighting Committee's recommendation that an electrical engineer be appointed to take charge of the Vestry's electric lighting station at a salary of £200 per annum has been adopted. Some difference of opinion exists between the members of the Vestry and the London County Council as to the terms of and conditions under which a loan is to be granted for the electric lighting works. The Vestry propose £25,000, which has been reduced to £23,500 by the County Council. A proposal that in the thoroughfares where mains for private lighting are now being laid mains for public lighting should be put down contemporaneously, was met by the objection that Mr. W. H. Preece advised that it would be better to await the result of certain experiments now being made in various quarters, in order that considerable savings which were anticipated might be made.

HANLEY (STAFFS.).—Designs for the electric light fittings for the Town Hall and Victoria Hall, submitted to the County Council by Messrs. Spagnoletti and Crookes, have been approved. It has decided to insure the three boilers at the electric lighting station at £3,000.

HOTEL LIGHTING.—The Forsyth Hotel, Aberdeen, is now lighted throughout by electricity by means of 200 16-c.p. incandescents.

IMPORTANT TRADES UNION CASE.—At Clerkenwell Police Court, before Mr. Horace Smith, Edward Stallard, late treasurer of the Bristol Branch of the Electrical Trades' Union, was summoned for unlawfully withholding the sum of £9. 10s. 4d. belonging to the Union. At the commencement of the proceedings a plea of *res judicata* was raised, counsel for the defendant producing a certificate of dismissal signed by the Bristol magistrates, who had previously tried the same matter. Eventually the magistrate said he could not do otherwise than decide the case in favour of the defendant, and dismissed the action.

KENSINGTON (LONDON).—A letter has been received by the Vestry from the Notting Hill Electric Lighting Company notifying the Company's intention of applying for a Provisional Order to empower them to supply electric current in the area recently abandoned by the House-to-House Electric Light Supply Company in the northern part of the parish. The letter was referred to the Electric Lighting Committee.

MOSS SIDE.—Mr. A. Marr, of the Collier-Marr Company submitted a proposal at the last meeting of the Local Board for lighting by electricity several of the principal thoroughfares of this district. He undertook to supply illuminating power of 10,628 candles to replace the present 2,026 candles, at a cost of £535 per annum. The proposal is to be made in writing, and discussed at the next meeting of the Board.

NEWPORT.—The County Council have had under discussion the description of lamp-post to be used for the arc lamps for the lighting of the streets. It has been decided to use bracket lamp-posts, for which designs are now being submitted.

NOTTINGHAM.—The works in connection with the new electric lighting station in Wollaton-street are approaching completion. The various buildings are nearly finished, and the chimney is all but complete.

OFFICE AND WAREHOUSE LIGHTING.—Many of the new sets of warehouses and offices built upon the site of the late extensive fire at St. Mary Axe, London, are being installed throughout by the electric light, and Messrs. Gilbert and Co., of Kensington, have lately received several contracts for wiring the buildings.

PLYMOUTH.—Owing to the opposition of the Plymouth Borough Council, the local gas company have withdrawn the power sought under their Plymouth Gas Bill to obtain a Provisional Electric Lighting Order to supply Plymouth with electric current. The Corporation is therefore now in sole possession of this power. The Council have, in addition, been successful in considerably reducing the amount of capital to be raised by the gas company under its new Bill.

PRESENTATION.—The employés of the firm of Messrs. Peto and Radford have presented Mr. William Peto with a handsome silver salver on the occasion of his marriage.

RAILWAY CARRIAGE LIGHTING.—The Bristol Electric Safety Lamp Works have just completed an order from the Agent-General for the Cape of Good Hope for 40 sets of self-contained electric accumulator lamps, arranged for hanging to the panels of the compartments of railway carriages, and also an order for corresponding fittings for 120 compartments. These lamps weigh about 12lb. each, and consist of a flat accumulator in polished wooden cases, the lamp being fixed in front at an angle of 45deg. It is claimed for these lamps that they can be fixed at a moment's notice, will burn for 15 hours continuously, giving light of about 4 c.p. in front of the reflector. The lamps have been subject to tests for the past two years, and it is stated that this order is the result.

RICHMOND.—The Electric Lighting Committee reported to the Town Council at the last meeting the receipt of a report from Messrs. Urquhart and Small on the electric lighting of the borough and the works of the Richmond Electric Light and Power Company (Limited), and certain recommendations made by the Committee were approved by the Council.

ROYAL AGRICULTURAL SHOW.—This important gathering is now being held at Cambridge, and will remain open up to and including the 29th inst. Messrs. Crossley Brothers have on view a number of their well-known gas and oil engines, including a 25-H.P. latest improved type Otto gas engine, capable of indicating about 65 H.P. at a speed of 160 revolutions per minute. This engine is of the new patent permanent tube type, and is fitted with timing valve, safety starting gear, quiet air suction, and sensitive high-speed governor. There is also on show a horizontal high-speed electric light gas engine of 2½ H.P. on the brake, running at a speed of 300 revolutions per minute. This engine is fitted with two flywheels, and is specially adapted for electric lighting purposes. Other exhibits include a 9-H.P., 3-H.P., and a ½-H.P. single-cylinder vertical gas engine. A number of oil engines are also exhibited from 10 H.P. nominal, to 2 H.P. nominal. One of these—a 4-H.P. engine—is entered for competition in Class I. Another, of 6-H.P. nominal, which has a water-vessel for cylinder-cooling purposes and an oil tank combined, is entered for competition in Class II. The total weight of this 6-H.P. portable engine is, in travelling order, 3¼ tons, and it is equal to a continuous working load of 11 H.P. effective. The engine works on the Otto cycle, and is of similar construction to the stationary oil engine made by the firm. Under the framing of this engine are two tanks—one for oil and one for the cooling water. The oil is pumped up by a small pump into a special measuring apparatus, for which a patent has recently been applied. The feature of this measuring apparatus is that the quantity of oil for working strokes following other working strokes is slightly increased for working strokes not previously followed by a

Digitized by Google

working stroke, which is a similar principle to that of the well-known Crossley gas engine, which renders this special measuring apparatus of much importance. Only a small quantity of cooling water is necessary.—Another effective exhibit is that of Messrs. W. H. Willcox and Co., who have on show a large variety of engineers' tools, lubricating and cylinder oils, and general engineers' stores.

SALISBURY.—Mr. E. R. Dale has just opened an electric charging station at 100, Bedwin-street, where cyclists, the police, postmen, &c., have the batteries for their portable lamps recharged. In the neighbourhood of Salisbury and Blandford many cyclists are adopting electric lamps.

SHOREDITCH (LONDON).—The Vestry having, as stated in our last issue, decided to purchase the Pitfield-street site for the electric lighting station, will petition the Board of Trade for an extension of the term of their Provisional Order for 18 months, in order to complete the electric lighting scheme, which is estimated to cost, with the dust destructor and other items, more than £100,000.

SOUTHPORT.—The Gas and Electricity Committee recommend that the price to be charged for electric energy for the first year, from the opening of the works, be 7d. per unit. The recommendation was approved.

TAVISTOCK.—The first annual meeting of the Tavy Iron and Engineering Works at Tavistock was held last week, and after declaring a dividend of 7½ per cent. for the year, Mr. J. Dennis, the chairman, said the Company had under consideration the question of the electric lighting of their works. Statistics were being collected in order to ascertain whether lighting by electricity could be started in Tavistock. They had water power quite sufficient for the purpose.

THEATRE LIGHTING.—A proposed new theatre, to accommodate an audience of nearly 17,000 persons, is to be built at Walsall, at an estimated cost of about £8,000, and is to be lighted throughout by electricity.——At Leeds Mr. Wilson Barrett has decided to build a new theatre capable of accommodating 2,000 persons, which is to be lighted electrically.——The Theatre Royal, Bradford, is now lighted almost entirely by electricity. Two 16-H.P. Crossley gas engines are used. The main switchboard is provided with a mechanical arrangement patented by Messrs. Ullathorne and Hartley for controlling the distribution as between the two engines in a manner stated to effectually guard against all possibility of a breakdown.

TOTTENHAM.—A letter received by the Local Board from the Tottenham and Edmonton Electric Light and Power Company, giving notice of their intention to apply for a Provisional Electric Lighting Order, was at the last meeting of the Board referred to the General Purposes Committee.

WINDERMERE.—It is stated that the Windermere Electric Lighting Company have secured a mill recently used as a woollen manufactory, for the purposes of an electric lighting station at Backbarrow, and that the premises are to be adapted for plant for electric lighting purposes which is to be shortly put down. It is stated that the site has several natural advantages, including a large quantity of water suitable for power purposes, and will form an excellent centre for distribution.

WORCESTER.—It has been decided to obtain an estimate of the cost of wiring and fitting up the Public Hall for the electric light. A new arrangement has just been entered into with the gas company under which, should the Corporation desire to discontinue the lighting of any of the lamps, an allowance of 5s. per lamp is to made to the Corporation.

WORKS LIGHTING.—The extensive iron works at Glengarnock are now lighted electrically.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

May 21, 1894.

9,862. W. MORISON. New York. Improvements in batteries.*

May 22, 1894.

9,896. G. W. LEECH. London. Improvements in the arrangement of gearing for electrically-propelled vehicles, cars, yachts, and launches.

9,909. E. W. LANCASTER. Birmingham. Improved shade-carrier for gas and electric shades.

9,927. E. J. PIPER. London. Improvements in electrical switches and connecting to the same.

9,934. G. E. ADAMS. London. Self-generating electro-magnetic motor for driving power.

9,949. T. CRANEY. London. Improvements in electrolytic apparatus.*

9,967. C. A. DAY. London. Improvements in electric arc lighting. (The Higham Electric Company, United States.)*

9,968. E. A. SPERRY. London. Improvements in the method of, and apparatus for, arresting motion of electrically-propelled mechanisms.*

9,974. W. P. THOMPSON. Liverpool. Improvements in, or relating to, apparatus for heating metals electrically. (C. L. Coffin, United States.)*

9,975. W. P. THOMPSON. Liverpool. Improvements in the method of, and apparatus for, heating, welding, or working metals by electricity. (C. L. Coffin. United States.)*

May 23, 1894.

9,999. W. MCGEOCH, jun., and A. W. STEWART. Glasgow. Improved holder for incandescent lamps.

10,021. S. W. MAQUAY. London. Improvements in connection with primary batteries and portable electric lamps.

10,044. A. THEODOLI. London. An improved system of producing luminous electric changeable writing, and in apparatus therefor.*

10,045. J. B. ORMSBY and G. H. BANISTER. London. An improved method of and apparatus for controlling the action of electric motors and other prime movers.*

May 24, 1894.

10,114. B. PELL. London. An improvement in incandescence electric lamps.

10,115. A. C. COSSOR. London. Improvements in electric lamps for surgical purposes.

May 25, 1894.

10,132. J. EDMONDSON. Halifax. Automatic zero reading electric instruments.

10,140. W. HARTNELL. Leeds. Improvements in regulators for electric currents.

10,149. J. ORME. London. Improved apparatus for supporting electrical conductors, and the like.

10,169. G. R. BLOT. London. Improvements in plates for secondary voltaic batteries.*

10,171. P. A. NEWTON. London. Improvements relating to writing telegraphs. (E. Gray, United States.)*

10,172. E. HOPKINSON. London. Improvements in or connected with vehicles for electric railways or tramways.

10,186. E. NASHOLD. London. Self-locking cleats for electric wires.*

10,199. J. W. NAUGHTON. London. An improvement in the art and process of electrotyping.*

May 28, 1894.

10,228. W. H. HILL-HARTLAND. Sheffield. Improvements in deodorising and purifying sewage or other waste liquors containing organic matters, in combination with generating and storing electricity, and in means or apparatus therefor.

10,242. W. HEARN and C. R. GATEHOUSE. London. An electric switch.

10,292. J. MANGER and E. MAJON. London. A novel mode of illuminating watches, clocks, compasses, barometers, and similar instruments boxed up in metal cases, by means of electricity.

10,293. J. MANGER and E. MAJON. London. A portable electric lamp.

10,331. F. B. BEHR. London. Improvements in conductors for electrically propelled tramway and railway vehicles.

10,332. S. J. SUTER. London. An improvement in regulating apparatus for electric arc lamps.

10,353. J. MORRIS, jun. London. Improvements in pendant fittings for electric lamps.

10,364. E. DRAGOUMIS. London. Improvements in electrical devices suitable as meters, motors, dynamometers, and the like.

May 29, 1894.

10,384. G. S. ORSON. Belfast. Improved carbon for electric lighting and other electrical purposes.

10,386. F. FRITZ. Manchester. Improvements in or applicable to clocks for operating electrical alarms.*

10,425. J. A. KINGDON. London. Improvements in electrical transformers.

10,426. J. A. KINGDON. London. Improvements in dynamo-electric machines.

May 30, 1894.

10,463. J. M. MOFFAT. London. Improvements in cells or boxes of electric batteries.

10,487. H. W. SULLIVAN. London. Improvements in electrical measuring and signalling instruments.

10,490. J. PLATT. Cleckheaton. Improvements in the method of and apparatus employed for heating steel wire by electric currents.

10,515. W. H. FLEMING. London. Improvements in dynamo brushes. [Date applied for under Patents, &c., Act, 1883, Sec. 103, November 13, 1893, being date of application in United States.]

May 31, 1894.

10,565. S. P. THOMPSON. London. Phase transformers for electric currents.

1894.

2,048. VOIGTLÄNDER. Dynamometers.
2,866. WISE (Lewis). Dynamo-electric machines.
3,108. LEFFLER and CORRIGAN. Electric railways.
4,244. DICKINSON. Overhead electric tramways.
5,474. DAVY. Electric arc lamps.
5,816. LAKE (Weston). Electrical measuring instruments.
5,971. ADAMSON. Using electric light for photography.
6,491. PITT. (Blondel and others.) Converting electric currents.
6,606. ALLISON. (Electrical Specialty Company.) Controlling electric lights.
7,215. MAGNIN. Electric printing telegraph apparatus.
7,307. BALBIANI. Electrical alarm.
7,617. COX. Thermo electric generators.

NEW COMPANIES. STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1894, pages 274-300, *&c., &c.*]

CENTRAL CHILI COPPER COMPANY (LIMITED).—This Company was registered on June 15th with a capital of £255,000 divided into 30,000 £6 per cent. Priority and 225,000 Ordinary shares of £1 each, to carry into effect an agreement made between the Panulcillo Copper Company (Limited), Sir John Pender, G.C.M.G., M.P., Francis J. Johnston, and Frank W. Bond, the liquidators thereof, and the present Company, for the sale to this Company of the goodwill of the business and all the assets of the said Panulcillo Copper Company (Limited), and to carry on the business of raising, crushing, smelting, washing, reducing, amalgamating, working and winning ores, metals, minerals, and mineral substances of all kinds. The first Directors are: Sir John Pender, G.C.M.G., M.P., Eugene A. J. Goldschmid, and J. H. Collins, F.R.S.

GOWERTON FOUNDRY COMPANY (LIMITED).—This Company was registered on June 14th with a capital of £10,000 in 200 shares of £50 each, to acquire the business of engineers carried on at the Gowerton Foundry and Engineering Works, Gowerton, near Swansea, South Wales, under the style or firm of "Henry Marker and Son," and to carry on the business of mechanical, electrical, and general engineers, manufacturers of and dealers in electric light fittings, art metal workers, fitters of electric bells, telephones, signalling apparatus and appliances, &c.

HEMMING AND COMPANY (LIMITED).—This Company was registered on June 12th with a capital of £25,000 in £5 shares to acquire and take over on and from January 31st the business of T. L. Hemming and Company (Limited), of 88, Snow-hill, Birmingham, and to carry into effect an agreement dated May 14, 1894, between T. L. Hemming and Co. (Limited), Thomas L. Hemming, and Stephen Wright, and to carry on the business of mechanical, chemical, electric, scientific, and general engineers, electricians, designers, and constructors, illuminating contractors, manufacturers of and dealers in iron, steel, brass, and other metals, manufacturers of all kinds of machinery, engines, motors, dynamos, electric appliances, &c. The first Directors are John Thornton, Thomas L. Hemming, Samuel Tonks, Charles T. Bishop, and Thomas R. Canning.

LLANDUDNO ELECTRIC SUPPLY COMPANY (LIMITED).—This Company was registered on June 18th, with a capital of £15,000, in £10 shares, to carry on within the district of the Llandudno Improvement Commissioners the business of an electric supply company in all its branches; and to carry on the business of electricians, mechanical engineers, suppliers of electricity for the purposes of light, heat, motive power, or otherwise, and dealers in electrical apparatus, &c. The subscribers (with two shares each) are:—Richard Conway, John Bellis, John Smith, James Nicol, William E. Jones, W. R. Nicol, and W. Arnold (all of Llandudno).

ARTHUR LEE AND SONS (LIMITED).—This Company has been registered with a capital of £30,000, in £10 shares, to acquire the business hitherto carried on by James Fairbrother and Co. (Limited), steel converters and refiners, wire drawers, &c., and to develop and extend the same.

F. H. ROYCE AND CO. (LIMITED).—This Company was registered o June 14th, with a capital of £30,500, divided into 30,000 Ordinary and 500 Deferred shares of £1 each, to acquire and take over as a going concern the business carried on by Frederick H. Royce and Ernest A. Claremont, under the style or firm of F. H. Royce and Co., at Cooke-street, Hulme, Manchester, and generally to carry on the business of manufacturing electricians and mechanical engineers. The subscribers, with one share each, are:—Frederick H. Royce, Ernest A. Claremont, A. W. Claremont, John de Looze, Mrs. Edith Claremont, Mrs. M. G. Royce, and F. Himus. The first Directors are Frederick H. Royce and Ernest A. Claremont, who are also managing Directors, and who may remain in office so long as they are willing to act.

RONALD A. SCOTT (LIMITED).—This Company was registered on June 15th, with a capital of £10,000, in shares of £1 each, to acquire the goodwill, machinery, rights, privileges and other property of Ronald A. Scott, of Acton Hill, in the county of Middlesex, and to carry on the business of electricians, mechanical engineers, electrical engineers and general contractors, and such other business as the Company may from time to time determine. The subscribers (with one share each) are:—Ronald A. Scott, Mrs. Annie Scott, Godfrey Wolley, George Heaver, James H. Garratt, T. H. J. Watts, and James Darner. The business of the concern is to be carried on by a manager or managers, the first of whom is Ronald A. Scott.

Digitized by Google

KERBEY BOWEN (LIMITED).—The statutory return of this Company, made up to January 30th, was recently filed. 956 shares, out of a nominal capital of £20,000, in £10 shares, have been taken up, and of these 800 have been issued as fully paid to Kerbey D. Bowen, electrical engineer and electric launch manufacturer, of 55, Regent-street, London, W., whose business has been acquired by the Company. Upon the remaining 156 shares the full amount has been called, resulting in the payment of £1,500, and leaving £60 in arrears.

LANCASHIRE AND YORKSHIRE ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of this concern, made up to July 12, 1893, was recently filed. Out of a nominal capital of £100,000, in £5 shares, 127 have been taken up. Upon each of these calls amounting to £2. 10s. per share have been made, resulting in the payment of £315, and leaving £2. 10s. in arrears.

NATIONAL ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of this Company, made up to March 14, 1894, has just been filed. The nominal capital is £100,000, divided into 100 Founders' and 19,900 Ordinary shares of £5 each. All the Founders' and 10,505 Ordinary have been taken up, and the full amount called, resulting in the payment of £53,010, and leaving £15 in arrears.

OGMORE VALLEY ELECTRIC LIGHT AND POWER SUPPLY COMPANY (LIMITED).—The annual return of this Company for 1893, made up to March 25, 1893, was recently filed. Out of a nominal capital of £10,000 in £5 shares, 634 shares have been taken up, and the full amount called on each, resulting in the payment of £2,287. 10s., and leaving £882. 10s. in arrears. The annual return for 1894, made up to March 27, 1894, was filed with the foregoing; 710 shares have been taken up, and the full amount called. The calls paid amount to £3,313, leaving £237 unpaid.

ORME'S ELECTRIC SIGNAL SYNDICATE (LIMITED).—The statutory return of this Company, made up to November 16, 1893, was filed on April 6, 1894. Out of a nominal capital of £7,500, in £1 shares, 6,350 have been taken up, of which 6,000 were issued as fully-paid to John Orme, in consideration for Patent No. 20,742 of 1891, and Provisional Patent No. 3,518 of 1893, granted to him for inventions relating to "electric and automatic signals." Upon the remaining 350 shares the full amount has been called and paid.

OSWESTRY ELECTRIC LIGHTING AND POWER COMPANY (LIMITED).—In explanation of their failure to file the required return, a letter from W. W. Coulson, of Oswestry, writing on behalf of the Company on June 9, 1894, states that pending the granting of the Provisional Order no allotment has been made.

OXFORD ELECTRIC COMPANY (LIMITED).—The annual return of this Company, made up to March 24, 1894, has just been filed; 6,586 shares have been taken up, out of a nominal capital of £100,000 in £5 shares. Upon each of these shares the full amount has been called, resulting in the payment of £32,930. The Electric Construction Company (Limited), of Queen-street-chambers, Queen-street, London, E.C., hold 6,401 shares, while 25 shares are held by residents of Oxford.

WATERHOUSE ELECTRO-METRIC SYNDICATE (LIMITED).—The statutory return of this Company, made up to December, 15, 1893, was filed on June 13th. The Company has a nominal capital of £20,000, divided into 1,000 Vendors' and 1,000 Ordinary shares of £10 each, of which 1,000 Vendors' and 260 Ordinary have been taken up. All the Vendors' shares were issued as fully-paid to Addison G. Waterhouse, electrician, of 127, Cromwell-road, London, S.W., and A. T. Salisbury-Jones, of 33, Old Broad-street, London, E.C., as part payment for certain patented inventions relating to the controlling and measuring of electricity sold to the Company. Upon the 260 Ordinary shares the full amount has been called, resulting in the receipt of £1,600, leaving £1,000 unpaid.

WILLANS AND ROBINSON (LIMITED).—An agreement dated May 7, 1894 (filed the following day) between Willans and Robinson (Limited), incorporated in 1888 (referred to as "the old Company"), and John Baker, of Billiter House, Billiter-street, London, E.C., the liquidator of the old Company, and the new Company, provides for the allotment as fully paid of 14,462 Ordinary shares of £5 each, Nos. 8 to 14,469 inclusive, and 14,463 £6 per cent. Cumulative Preference shares of £5 each, Nos. 30,001 to 44,463 inclusive, to the members of the old Company, in accordance with the Reconstruction Agreement dated March 9, 1894.

CITY NOTES.

AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED).—The coupons on this Company's Four per Cent. Mortgage Debentures to bearer, due July 1st, will be paid on and after July 2nd, at Parr's Banking Company and the Alliance Bank (Limited), Bartholomew-lane, London, E.C. Coupons must be left three days for examination. The debenture register will be closed from the 25th to the 30th inst. inclusive.

ANGLO-PORTUGUESE TELEPHONE COMPANY (LIMITED).—This Company notifies that Coupons No. 13 of the First Mortgage and No. 8 of the Second Mortgage Debentures will be paid, less income-tax, by Parrs' Banking Company and the Alliance Bank (Limited) on and after 2nd prox.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The coupons on this Company's second issue of Five per Cent. Debentures, due on the 30th inst., will be paid on and after that date at Parr's Banking Company and the Alliance Bank (Limited), Bartholomew-lane, London, E.C. Coupon must be left three days for examination.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended June 17th were £831, as against £782 in the corresponding period of 1893, being an increase of £49. The total receipts for the half-year amount to £21,754, as against £21,035 for the corresponding period of 1893, an increase of £719.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The transfer books of the 5 per cent. redeemable debenture stock of this Company will be closed from the 23rd to the 30th inclusive, for the purpose of preparing interest warrants.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—Notice is given that an extraordinary general meeting of this Company is to be held at the Cannon-street Hotel, E.C., on Tuesday, July 3rd, at 12:15 o'clock, to consider and pass the resolution adopted at the meeting of the Swan United Company last week.

GREAT NORTHERN TELEGRAPH COMPANY.—The coupons of this Company's shares falling due on July 2nd will be paid by Messrs. C. J. Hambro and Son, of 70, Old Broad-street, London, E.C., on and after that date. Coupons should be left three days for examination.

GULCHER (NEW) ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—An extraordinary general meeting of this Company was held on Tuesday last at Winchester House, Old Broad-street, E.C., Mr. D. De Castro presiding. The Secretary (Mr. T. C. Morgan) having read the notice calling the meeting and the minutes of the previous meeting, the Chairman said that the shareholders had been brought together to confirm the resolutions passed at the extraordinary general meeting of the Company held on June 4th for the purpose of winding up the Company voluntarily and of appointing Mr. Charles Fitch Kemp liquidator. He, therefore, without further comment, proposed that those resolutions should be confirmed. A shareholder seconded the motion, which was agreed to unanimously, and the proceedings ended.

HOBART ELECTRIC TRAMWAY COMPANY (LIMITED).—The first annual general meeting of this Company is to be held at the offices, College-hill Chambers, Cannon-street, E.C., on Wednesday, the 27th inst., at 2:30 p.m.

HUMPHREYS (LIMITED).—The Directors of this Company have declared a half-yearly dividend of 7 per cent. per annum on the Preference shares, and 10 per cent. on the Ordinary shares, carrying forward £2,000. The reserve fund now amounts to £10,000.

MEDICAL BATTERY COMPANY (LIMITED).—The creditors, shareholders, and debenture-holders of this Company have held a meeting at the Inns of Court Hotel, London, W.C., to consider a scheme of arrangement whereby the business is to be carried on in future. Mr. Warley (the Assistant-Receiver in the liquidation proceedings) presided, and Mr. Jerome gave details of the scheme, from which it appeared that a new company is to be formed under the style of the Medical Electrical Institute (Limited), or similar name, with a capital of £75,000 in 25,000 £1 Preference shares and 20,000 Ordinary shares of £2. 10s. each, with power to increase or reduce this number. The Preference shares are 7 per cent., and are to be issued to creditors of the Medical Battery Company in payment of their claims. The new Company is to take over all assets and such sum of money as may be in the hands of the Receiver for the debenture-holders, after deducting certain costs and expenses. Six Directors are to be appointed—two to be creditors' representatives. In the event of another winding up being necessary the creditors are to have a first charge on the assets. Mr. Jerome stated that the business had been carried on recently, and had just paid expenses. But it had only been continued for the purposes of realisation, and in order to complete existing contracts. No attempt had been made to carry on the business in the ordinary sense of the term, and the wares had not been advertised in any way. If the scheme were approved the business could be resuscitated, and carried on in a manner that would defy further attacks. On the methods by which these attacks are to be defied, and on the style of business to be carried on in future the scheme was, so far as we can discover, silent; and it will be a gross scandal if the Harness quackery is to be continued under a scheme which has, presumably, the sanction of the authorities of the Bankruptcy Court. A creditor wished to move a vote of confidence in, and sympathy with, Mr. Harness, but was ruled out of order, and no such resolution was put. Resolutions were, however, passed at each meeting unanimously accepting the scheme; and it therefore appears likely that another crusade will be necessary before electrical science will be rid of this attempt to associate its name with the "electropathic" belt business. Unless some radical change in the method of doing business is contemplated by the new Directorate, it should not be difficult for, say, the Institution of Electrical Engineers or the British Medical Association to obtain an injunction against the use of the name selected for the reconstructed company, which will undoubtedly be more misleading to the general public than the original company was proved to have been.

PACIFIC AND EUROPEAN TELEGRAPH COMPANY (LIMITED).—The coupons in this Company's Four per Cent. Guaranteed Debentures, due 30th inst., will be paid on and after that date at Parr's Banking Company and the Alliance Bank (Limited), Bartholomew-lane, London, E.C. Coupons must be left three days for examination.

WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED).—The coupons due on June 30th on the debentures of this Company will be paid by Messrs. Barclay and Co., Lombard-street, E.C. Coupons should be left two clear days for examination.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended June 15th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £2,379.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the two weeks ending June 15th were £2,181, as compared with £2,719 for the corresponding period of last year. The receipts for February, estimated at £4,946, realised £4,942.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 841.—Vol. XXXIII. FRIDAY, JUNE 29, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/*

NOTES.

In a leading article in our issue of March 9th we adverted to the then recent decision of the London County Council, that all loans made to the London vestries for electric lighting purposes should be repaid within a period of 25 years; and we pointed out that there were one or two sound reasons for, and advantages in, adopting this course. The stand made against this policy by the would-be parochial borrowers has, however, already induced the County Council to throw over its own Finance Committee, and adopt the 42-year period of repayment in the case of the Hampstead Vestry loan. The immediate result of this step ought certainly to be an appreciable reduction of the price of the metropolitan municipal unit; that is to say, if parochial management be really all that it is claimed to be.

One of our leading articles this week discusses some modern views on the theory of electro-chemistry, in relation to an interesting Paper by Prof. Ostwald, which we also publish. We cannot refrain from noticing one or two practical matters in this Paper, which, though aside from theory, are worthy of attention. Prof. Ostwald, while throwing new light upon the phenomena of primary batteries, has pointed out the direction from which the successful commercial primary battery must be expected to come. It must be a battery developing electrical energy from carbon without the intervention or aid of any heat transformations. Prof. Ostwald's advice amounts to a recommendation to renounce the heat engine and all its works. Advocates of primary batteries, as they exist at the present time, sometimes argue that, although these batteries consume zinc, they really consume carbon or coal, since coal is used in the manufacture or recovery of the zinc. They therefore claim that a zinc battery is in reality a carbon engine. Such a battery, however, is not a carbon engine in Ostwald's sense, for it involves a relation between the zinc and the fuel which is not independent of heat, and which must therefore suffer from those defects and that inefficiency from which heat-energy operations are inseparable.

On the other hand, those who are inclined to disparage the claims of the primary battery, *per se*, as an electric engine should look to the ground beneath their feet to make sure that it is not too thin. The absence of the carbon engine, in the Ostwald sense, rests entirely upon the accident of certain chemical relationships remaining yet undiscovered. No one believes that their discovery is a physical impossibility. At the same time, Prof. Ostwald himself admits that he has no presage of the practical solution. It is far easier to say what Jablochkoff should not have done than to indicate what he ought to have done. The best that can be done is to indicate a parallel. But parallels, where the first term is a Bunsen cell and the third term a hypothetical carbon engine, do not advance the practical side of the question very much. Nevertheless, the question is one the solution of which involves great issues, industrial and social; and we quite agree with Prof. Ostwald in thinking that "had we a cell in which electrical energy was produced by the direct oxidation of carbon with an output approaching the theoretical, we should be on the brink of an industrial revolution, compared with which the invention of the steam engine sinks into insignificance." Such a cell should yield nearly six H.P. hours, or four electrical supply units per pound of carbon which opens up a potentiality of cheapness beyond the dreams even of Mr. Preece.

The article by Mr. Kennelly which we publish this week is a useful contribution to the methods of calculation at present available for alternate-current problems. The treatment of vector quantities in the manner described has been long known to mathematicians, but Mr. Kennelly has been the first to show the applicability of the method to such problems as the one here considered. Fortunately, the majority of alternate-current problems, when mathematically considered, are not found to involve the hyperbolic functions or a number of vector qualities. As a rule, it is quite sufficient to consider the two components of these vectors in phase and in quadrature with the current, and in such cases the complication introduced by having to consider not only the magnitude of the vector but its phase angle can be avoided. But when, as in the present problem, a large number of vectors is involved, the method of Mr. Kennelly is very useful, and the signs which he has introduced to denote the phase angle of any vector are most convenient. As regards the result in the present problem, it is interesting to see that, as nearly always happens when alternate-current problems are attacked numerically, it is possible to reduce the formulæ to a comparatively simple form, owing to the fact that when the complicated functions are examined, and their relative values are considered, it is seen that they can, for the most part, be neglected.

It may be objected to the synchronising method invented by Mr. J. W. Jones, and described by him in another column

Digitized by Google

that the Aron meters to which it has been successfully applied are almost out of date. A new Aron meter with short pendulums and an automatic starting and driving-gear has been introduced, but a large number of the old instruments are in daily use, and form a serious item in the plant of the supply companies, though one which earns a steady and handsome revenue. Pending the long-delayed pronouncement of the Board of Trade as to the types of meter which will succeed in obtaining certificates, the supply companies are at liberty to put any kind they please into the consumers' houses, and the longer the official decision is postponed the more difficulties are likely to arise as to the use of meters which have failed to meet with approval. Whether the old type of Aron is likely to be approved or no is of small importance compared with the efficient maintenance of a stock of many hundreds. The objection to the periodic winding is not so great as inventors of motor meters would have us believe. The range is pretty good, and the serious fault is the slow movement, which is not infrequently produced by slight want of synchronism of the pendulums, resulting in a false registration on the dials. That a meter should be liable to record a few pennyworths of current per quarter, when no current whatever had been passed, has been regarded as a more serious fault than an error of 5 or 10 per cent. on an average load. Mr. Jones's remedy is an extremely simple one, and possesses several points of interest which have not been touched upon in his article. Two pendulums slightly out of synchronism, if thus magnetically yoked together, vibrate with a continually altering difference of phase gradually attaining a maximum, and then reversing, never exceeding a certain amount. The mean period of each pendulum taken over a considerable number of beats is identical. If not thus yoked, the phase would continuously and progressively alter.

The claim which is advanced, that the most unique and striking feature of the "S.K.C." motor system—which we describe this week—is the use of condensers, may be justifiable enough in regard to American practice; but it certainly is not true that the use of the condenser in this system has any novelty when European as well as American practice is considered. Continental and British manufacturers long ago used electrostatic condensers in conjunction with alternate-current motors; and some of these makers have advanced a step further — they have abandoned them. The necessity for a condenser, or some other device to prevent the "false currents" or "wattless amperes," as they are variously called, from surging in and out of the line and making everybody's lights pump, is rather a confession of an inherent weakness in this type of motor. People, of course, do not want their lights to pump whenever a motor is started on the mains; but neither do the users of small motive power care to be bothered by all the trouble and inconvenience, and the extra cost of getting and maintaining this form of starting gear. What is required, and what would suit every party, is a type of motor which has not this electrical defect of what Artemus Ward would call "slopping over." Perhaps, if the motor must "slop over," electrically speaking, it is better that it should do so into a convenient condenser than into the neighbouring lamp leads.

A representative of the *Pall Mall Gazette* has been interviewing Prof. George Forbes on the subject of the Niagara power scheme. The Professor is thoroughly sanguine about the success of the scheme and the revolutionary influence it will exert upon the industrial features of the locality. Already the requests for the supply of power "come in from places as far distant as Albany, 350 miles away on the Hudson river." Perhaps this affords an explanation of the anxiety of some American mathematicians to find out how far the power of Niagara may be commercially transmitted, they want to see if they can reach that customer in Albany. Prof. Forbes and his colleagues have determined to make a solid job of their engineering works. "The massiveness of the masonry would stagger you." But, recognising that the old order changeth, giving place to the new, they have refrained from "building for eternity," as the Americans say we do with our railways. They have not designed their structures "to last much longer than 2,000 years." The "much longer" is delightful. In about that time—3,894 A.D., to wit—Nature will have done her little solid job, and will have eaten away the foundations of all that staggeringly massive masonry. For our own part we shall be relieved when the period of talk and interviewing is past, and glad when the two-phase alternators are generating energy to be delivered at Buffalo and elsewhere at a rate appreciably less than it can be obtained in the usual way. Then, and not before, engineers all over the world will be ready to recognise the commercial and engineering greatness of the Niagara scheme.

Royal Institution.—The general monthly meeting will be held on Monday next, at 5 p.m.

"Our Postal Telegraphs."—Mr. W. H. Preece is contributing a series of papers to *You and I* under the title of "Our Postal Telegraphs: The Wonderful Story of their Development."

Legalising Electrical Units.—The American House of Representatives has passed the Bill legalising the Chicago "international" ohm, volt, ampere, coulomb, farad, joule, watt, and henry.

Obituary.—The death is announced of M. Edmond Carré, who was the first to manufacture the hydraulically squirted electric light carbons invented by his brother, M. Ferdinand Carré.

Lux in Tenebris.—A German police regulation is said to read as follows:—"From the beginning of darkness every vehicle must have a lighted lantern. Darkness begins when the street lamps are lighted."

Electric Traction in Brussels.—The electric tramway in Brussels, which has been constructed by the Union Company in Berlin on the Thomson-Houston overhead-conductor system, was opened for traffic a few days ago.

British Association.—At a recent meeting of representatives of the principal educational bodies and other institutions in Toronto, it was unanimously decided to invite the British Association to hold a meeting there in 1897.

The Union of European Incandescent Lamp Manufacturers.—Representatives of the various glow lamp manufacturing firms held another meeting in Berlin last week, when further points as to the working of the Union were discussed.

The Telegraph in Kashmir.—The telegraphic party in Kashmir under Mr. Olphert's superintendence have crossed the passes and recommenced work, says the *Indian Engineer*, but the whole party suffered severely from snow blindness.

Digitized by Google

Cable Interruptions: Date of Interruption.

Bissao-Bolama	Nov. 24th, 1893.
Tarifa-Tangier	June 12th, 1894.

A Central Station on the Spree.—The Allgemeine Electricitäts Gesellschaft intends to commence during the present summer the erection of a central station on the Upper Spree, to supply current for lighting and power purposes to the Berlin suburbs.

The Canadian Pacific Railway.—According to *Engineering*, the Canadian Pacific Railway propose to use electricity for moving its trains over the Rocky Mountain division of the line. The method is to be tried first at the Kicking Horse Pass, where there is ample water-power.

Electric Treatment of Leather.—According to *L'Electricien*, an electrical process of colouring leather is being tried. The hide is stretched on a sheet of metal and covered with a layer of the colouring liquid. A current is passed, opening the pores of the hide, and allowing the colouring material to soak well in.

Scarborough.—The line connecting Scarborough with York by telephone was completed last Thursday week, but it is expected that a month will pass before it will be thrown open to the subscribers. Some delay has been occasioned by a fractious landowner, who refused to permit the line to cross his property.

Electric Traction in Panama.—The electric tramway which was laid down at Panama early in 1892 continues, according to the last report of the British Consul there, in successful operation. The line is on the overhead-conductor system, and traverses the entire length of the city along the principal thoroughfares.

The Berlin-Vienna Telephone Trunk Line.—It is stated that the Austrian Postal and Telegraph Department is now busy preparing the plans for the establishment of direct telephonic communication between Vienna and Berlin. The line, which it is expected will be completed by the autumn, will run *viâ* Prague, Bodenbach, and Dresden, the total distance being about 400 miles.

Society of Arts.—According to the treasurer's statement of receipts and expenditure for the year ending May 31, 1894, the income of the Society of Arts from all sources amounted to £9,748, subscriptions and life compositions accounting for £5,847. The expenses for the same period amounted to £8,428; the principal items being office £2,818, *Journal* £2,142, conversazione £640.

Electricity and Gas in Massachusetts.—According to the report of the Gas Commissioners of Massachusetts for the year ended June 30, 1893, there are 134 concerns under the supervision of the Board. Of these, 24 supply gas and electricity, 62 only the electric light, and 48 only gas. The aggregate receipts of the gas business amounted to £1,226,466, and those of electric lighting to £687,673.

Hastings and St. Leonards.—To-morrow evening at 10 o'clock, the Mayor of Hastings will formally switch on the arc lights on the sea front, extending from the Fish Market to the end of the Marina. The ceremony is to be performed at the Hastings pier head. Up to the present only 15 arc lamps have been in use on the sea front; but the extensions which are about to be inaugurated will include some 52 lamps.

Accident to Mr. Edison.—Mr. Edison met with an accident at his residence at Ogden, New Jersey, on Thursday last week. He was sitting in the porch of his house when the back of his chair broke and he fell down four steps. His injuries were thought at the time to be trivial, but on Saturday Mr. Edison felt pains in the side and back. A medical man who was consulted said the pains were probably due to an internal injury.

The Paris 1900 Exhibition.—The Paris correspondent of *The Times* reports that at the first meeting of the 1900 Exhibition Commission a scheme of classification was read. Group IV., which is devoted to "the *Matériel* and General Processes of Mechanics," comprises steam-engines, motors, various apparatus in general mechanism and implements. Group V. deals with electricity, including the production and mechanical application of electricity, electro-chemistry, electric lighting, telegraphy and telephony.

Unconscious Newspaper Humour.—Having found that more than once since the establishment of street arc lighting in Portsmouth the thoroughfares have been left in darkness, a local newspaper observes that this is all very well as showing the advantage of the arcs over no light at all, but that constant repetition of the phenomenon is irritating. The local contemporary recommends that the matter should be "rectified."

Farewell Dinner to Mr. Kapp.—We are glad to learn that it is proposed to give a farewell dinner to Mr. Kapp, who, as we have already chronicled, has been offered, and has accepted, an important position in Germany, and will, in consequence, be leaving England in August. It is the wish of many of Mr. Kapp's friends to mark, in some suitable way, their appreciation of his services to electrical engineering, and their regret at his departure. With this object it is proposed to invite him to a farewell dinner, on Monday, July 23rd, at 7:30 p.m, to be held at the Whitehall Club, and to present him with a souvenir.

Lamp Shades.—M. Dupré returns to the charge in *The Times* this week. He is of opinion that if Messrs. Crompton had as much experience in matters relating to so-called spontaneous combustion as he has they would not be astonished at their failure to bring about the necessary conditions in what was, probably, their first attempt at experimental research. The exact conditions to bring about the spontaneous ignition of such lamp shades may be difficult to bring about experimentally, but he, M. Dupré, thinks that there can be no doubt that the case recorded in his former letter was one of spontaneous combustion.

A Self-contained Car.—According to the *Electrical Review* of New York, a "Mr. W. H. Patton is again trying to boom his car, and has formed a corporation known as the Independent Electric Traction Company. Each car is supposed to be self-contained; that is, a gas engine is placed in the centre of the car, fed with gasoline from a tank overhead, and in turn drives a dynamo that charges a set of storage cells, from which current is supplied to a motor supported on the car axles. With the addition of a compressed air motor the car would only need a compartment to hold a team of horses to be of practical, if not commercial, utility."

The Electric Light and Overtime.—At the Westminster Police Court on Monday there was a batch of prosecutions against West End dressmakers and other employers for Factory Act offences, and substantial fines were inflicted in every case. In one instance, where the summons was for having a number of women at work after eight o'clock in a room of very insufficient cubic space, the defendant, who was from Sloane-street, maintained that he ought to be exempt from the regulations as he had been to the expense of putting in the electric light, which did not vitiate the air like gas. Mr. de Rutzen would not entertain this as an excuse, and imposed a fine of 40s. and the costs.

Edinburgh.—Prof. B. W. Kennedy lectured in the Albert Hall, Edinburgh, on Monday night, on "The Electric Light in Edinburgh." The lecture was of a popular nature, and was illustrated by limelight views. Prof. Kennedy, in explaining the Edinburgh system, said there would be ten trunk mains, each one ending in fifteen branching or feeding points, from which distributing mains would run under the pavement and afford a domestic supply by means of connections. After describing the central station at Torphichen-street, he stated that four miles of the city would be lighted by arc lamps, 175 of which the Council had sanctioned. The pillars, he said, showed an artistic design which had been supplied by the School of Applied Art, and adopted by the Council.

Wood-Fibre as an Insulator.—One of the best materials yet tried for underground conduits for electric wires, says Mr. Franklin L. Pope in the *Engineering Magazine*, is wood-fibre treated with an insulating and preservative compound, so as to form a dense, hard substance. The fibre is formed into tubes of 5ft. in length, and of any diameter from 1in. to 24in. by an ingenious machine recently invented for the purpose. Couplings, fittings, and section-boxes are made of the material. The

Digitized by Google

prepared wood is a perfect non-conductor of electricity and heat, and, when laid in the ground, is much more durable than iron, being unaffected by either acids or alkalies. One advantage, which will be appreciated by electricians, is that the material is easily cut by ordinary tools, so that joints or fittings can be inserted at any point where it is desired to connect a branch.

The City Lighting.—In a report on the works executed by the City Commissioners of Sewers, furnished by Mr. D. T. Ross, the recently-appointed chief engineer to the Commission, it is stated that the number of arc lamps now lighting in London is 479, and the total length of the thoroughfares lighted is 13 miles. There has been a proportionate reduction in the number of gas lamps lit, which is 1,315; it follows, therefore, that 2·74 gas lamps are extinguished for each arc lamp. The question as to the propriety of lighting the minor streets by the incandescent or glow lamps, and as to the relative cost of gas and electricity for that purpose, is still under the consideration of the Commission. This subject was reported upon by the late engineer at the beginning of last year. The City of London Electric Lighting Company has lighted experimentally the thoroughfares of Basinghall-street and Aldermanbury with incandescent lamps as an illustration.

Gas and Electric Light.—Mr. John West, in his Presidential Address to the Incorporated Gas Institute last week, was good enough to make some flattering remarks about electrical engineers and their influence on the standard of light required by the public. After considering some of the technical matters connected with gas lighting, the address goes on to discuss the altered circumstances of gas undertakings since the dawn of the era of cheap oil and electric lighting. There can be no doubt, says the *Journal of Gas Lighting* in its report of the address, that the influx of the able, keen, pushing engineers connected with the latter industry into the business of artificial lighting has had a marked influence upon the public with which they have had to deal. Without going so far as to say that the average electric light engineer is a smarter man than the average gas manager, it may be held that the former is the greater novelty. He has all the advantage that freshness confers upon a new cause; and he deals with the problems of lighting in a different style from that of a man who has hitherto regarded it as his sole duty to make gas. The electrician knows that electricity in itself has no interest for the consumer, so he sets himself to make it interesting in its applications. The gas manager has expected his public to be content with gas, and has troubled himself little with its applications.

Science and Popular Opinion.—The following cogent remarks on this interesting subject are from a speech made by Mr. A. J. Balfour on Wednesday evening last, at a meeting of the British Economic Association:—

The public have never yet mixed themselves up in scientific investigations without spoiling the investigations and doing themselves a good deal of harm. Take medicine. Perhaps it is flattering medicine to describe it as a science; at all events those who pursue it do their best to pursue it on scientific principles. But directly the public mix themselves in it, directly party feeling, which is an essential element in all popular feeling, arises, you have the most paradoxical, and in some cases the most disastrous results. . . . Science has often been proved wrong; instinctive, uneducated public feeling has in many cases been proved right. But I have no doubt that if you are going to allow questions of scientific interest to be decided by universal suffrage, you will not do much good to universal suffrage, and you will absolutely ruin science. For though science is often wrong, it can only get right and develop itself in the direction of truth by being allowed free play, outside the influence of those popular forces which tend to divert it out of a scientific direction. Fortunately for us, the other branches of science, closely as they are connected with the development of civilisation, are so far beyond popular interest or knowledge that the public are ready to leave them alone. I suppose if we could make a true diagnosis of the causes which have produced the great social improvement and development of the last 100 or 150 years, we should put at the very head of these causes, first, the growth of scientific knowledge in mathematical, in physical, and in other directions. But the public who have profited by these labours hardly realise themselves how much they have profited by them. At all events, they never venture to put their finger in the pie or to suggest to the mathematical physicist or chemist what view he ought to take of the properties of matter, or the mode in which energy can most usefully be applied. The public have left the scientific man alone. They have but vaguely understood the character of his labours; they have been content to profit by them without apprehending them.

The First Monopoly Patent.—The absence of reliable information concerning the history of patents for invention under the common law, says *Engineering*, has been noted with regret by several writers. The Statute of Monopolies in 1624 is known to have been based on the law declared in the case of "Darcy *v.* Allin" in 1602; but as this case in its turn appeals to decisions of a still earlier date, no definite conclusion can be drawn therefrom as to the period in which the first monopoly grants were made. The alchemical patent of Edward III., quoted by Hindmarch, proves on examination to be either a warrant for the arrest of two alchemists, or one of a series of dispensations from the law of Henry IV., by which the practice of multiplication was forbidden. The Commission appointed by Henry VI. to inquire into the feasibility of the philosopher's stone issued no report, and the alum patent cited by Farcy before the Parliamentary Committee of 1829 resolves itself into a permission to an Italian merchant to import a fixed quantity of that commodity. In default of facts, therefore, English and American writers have been driven to accept as genuine the theory of Collier, who, in his essay on "The Law of Patents," published in 1893, traced the origin of patent law to the charters of the Trading Companies and City Guilds. But these charters, which gave legal recognition to certain voluntary associations on the ground that they had existed from time immemorial, conferred no new rights. The patent, on the other hand, creates a right not otherwise recognised by law, the validity of which is practically decided on the question of the novelty of the manufacture therein claimed. The assumed connection, therefore, rests on no historical basis, and no apology will be made for an attempt to substitute a theory, the truth or falsity of which, at any rate, can be easily tested by the records themselves. As the result of a search, believed to be exhaustive, through the voluminous patent rolls of Elizabeth, it may be stated with some degree of confidence that the practice of granting monopoly patents was inaugurated in 1561. The subject of this first monopoly, we are delighted to hear, was a substance called "sope."

The Post Office and the Telephones.—Several questions on this subject were asked last week in the House of Commons. Captain Bagot asked the Postmaster-General whether an agreement between the Post Office and the National Telephone Company had been in preparation for two years; and whether, in view of the fact that he had stated on various occasions during the last year that the agreement would be shortly laid before the House of Commons, he could now state definitely before what date the agreement would be produced. The hon. member further asked the right hon. gentleman whether he was aware that the effect of the long delay in concluding the agreement, and the refusal of the Post Office in the meantime to grant licences to municipalities, had been to enable the National Telephone Company to increase their monopoly and place themselves in a better position than those municipalities which wish to obtain licences; and whether he would state how many applications for local licences from municipalities had been received since it was decided to purchase the trunk lines. Mr. A. C. Morton had a similar question on the Paper. Mr. Henniker Heaton asked whether the Postmaster-General would take care that any agreement between himself and the National Telephone Company should provide that, in the event of the purchase by the State of the Company's property, only the market value of the stock and plant actually belonging to the Company should be paid as consideration money, without taking into account prospective profits or any claim for goodwill, or any similar claim. Mr. A. Morley stated that since he answered a question on the subject on April 30th last further points of considerable complexity had arisen in connection with the settlement of the details of the agreement. He did not think that the delay had enabled the National Telephone Company either to increase their monopoly or to place themselves in a better position. With reference to the question of the member for Canterbury the Postmaster-General pointed out that the agreement now being negotiated was simply intended to give effect to the arrangement made by the late Government for the purchase of the Company's trunk wires—an arrangement which did not contemplate any interference with the general conditions of the existing licence.

ON IMPULSIVE CURRENT-RUSHES IN INDUCTIVE CIRCUITS.

BY ALFRED HAY, B SC. (EDIN.).

Introductory.

The object of the present series of articles is to give an account of experiments recently carried out (and still being continued) in the Engineering Laboratory of University College, Nottingham, on the abnormal rushes of current which sometimes occur when a transformer is suddenly switched on to live mains. The subject is one of great interest, from a practical as well as a theoretical standpoint, and it is hoped that the experiments about to be described will prove of interest as definitely establishing the nature of the action which takes place.

In carrying out the experiments I have been assisted throughout by Mr. W. B. Burnie, a senior student of the College, who not only constructed the greater part of the apparatus used, but spent much time and trouble in perfecting the arrangements and getting the apparatus into proper working order. The success of the experiments is largely due to his zeal and perseverance, and I here desire to acknowledge my indebtedness to him for his able and willing assistance.

§ 1. Since the publication of Dr. Fleming's paper on "Experimental Researches on Alternate-Current Transformers," read before the Institution of Electrical Engineers in November, 1892, it has become generally known that under certain conditions there is an abnormal rush of current into the primary coil of a transformer at the instant of connecting it to the supply mains. That such a rush of current might sometimes be expected was shown by Dr. Sumpner in a paper contributed to the *Philosophical Magazine* for June, 1887, and partially reproduced in Dr. Fleming's "Alternate-Current Transformer," Vol. I., pp. 263-268. The exact conditions determining a rush, as well as the nature of the effect produced, appeared, however, to be somewhat obscure. It therefore occurred to the writer that the most satisfactory way of settling the points at issue would be to devise some method of experimenting which would enable one to study the action in detail and trace the various stages through which it passes before a steady periodic state has set in. For this purpose a special form of switching apparatus was designed, which fulfils the following conditions:—

(1) The "make" or "break" of the switch are completed in an interval of time which is but a very small fraction of the whole period. By this means any such effect as a gradual "tailing-off" of the current at the instant of breaking, spread over a number of periods, is entirely avoided.

(2) The exact phase of the E.M.F. is known, both at the instant of switching on and off.

(3) The points on the E.M.F. curve at which the switch is closed and opened are capable of being varied independently.

(4) By combining this switching apparatus with an ordinary revolving contact-maker, the actual shape of the E.M.F. and current curves, both normal and those corresponding to a "rush," may be obtained.

§ 2. The description of the special switching arrangement referred to above will be deferred for the present; but the method of taking readings and the instruments employed will be briefly described. The alternator used in the experiments was a Ferranti alternator of the old type, with zigzag-wound armature. As constancy of excitation was of great importance in the experiments, the field of the alternator was excited by a number of small E.P.S. cells, the current being measured by a Siemens electro-dynamometer. Fig. 1 shows the arrangement of the apparatus. For measuring the instantaneous values of the potential difference at the transformer terminals, and the current through the primary coil, a quadrant electrometer of the Ayrton-Perry-Sumpner type was used. The magnetic control in this instrument was, however, abandoned for several reasons. The needle supplied by the makers was removed and replaced by another with a delicate phosphor-bronze strip suspension. The leaden vessel which is designed to contain the sulphuric acid was filled with a heavy mineral oil, and a disc of brass hung from the needle so as to be completely immersed in the oil. It was found that this arrangement rendered the instrument almost aperiodic, so that readings could be taken in quick succession, and the zero of the instrument obtained at any instant without much loss of time. In taking readings for the potential difference curve, the instrument was, of course, used idiostatically, and the arrangement of connections was as shown in dotted lines in Fig. 1. The full lines show the arrangement for taking current readings. A small non-inductive resistance, R, was placed in series with the primary coil of the transformer, and the potential difference at the terminals of R was measured by the electrometer, which in this case was used heterostatically.

The alternator was driven by a "Priestman" oil engine, the speed of which was remarkably constant (in spite of the fact that the engine was running light), the maximum deviation from the mean speed not exceeding 2 per cent.

§ 3. We shall begin our study of current-rushes by considering the comparatively simple case of a circuit of constant permeability, and shall then pass on to the more complicated case of a circuit containing iron. At first sight, it might be supposed that there is no analogy whatever between the two cases; it appears, in fact, by most people to be assumed that such a phenomenon as a sudden rush of current at the instant of closing the switch is only characteristic of circuits containing iron, and does not take place in the case of circuits whose

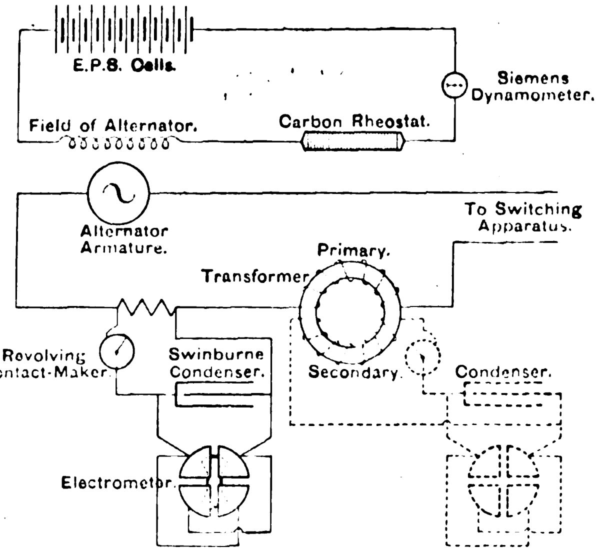

FIG. 1.

permeability is constant. The fallacy of this view will presently be made apparent. It will also be shown that what under certain initial conditions happens in the case of an inductive circuit not containing iron, is precisely of the same nature as the abnormal current-rushes in transformers, with the difference that the latter are considerably more complicated on account of the variable inductance and hysteresis of the material, and take place on a very much larger scale.

It will conduce to brevity and clearness in what follows if we define a "current-rush" as a definite numerical quantity; viz., the ratio of the maximum value reached by the current during any half-wave to the normal maximum when a steady periodic state has been reached. Thus, if by measurement we find that during its first half-wave the current reaches a maximum value of 3 amperes, and that its normal maximum is one ampere, we may say that the "current-rush" during the first half-wave is 3.

§ 4. Let r and L stand for the resistance and (constant) inductance of a circuit, and let a simple harmonic electromotive force $E \sin (pt + \alpha)$ be suddenly applied to the circuit. Taking the well-known differential equation

$$r i + L \frac{di}{dt} = E \sin (pt + \alpha), \quad . \quad . \quad . \quad . \quad (1)$$

and solving, we find

$$i = \frac{E}{\sqrt{r^2 + p^2 L^2}} \left\{ \sin [pt - (\theta - \alpha)] + e^{-\frac{rt}{L}} \sin (\theta - \alpha) \right\}, \quad (2)$$

Digitized by Google

the time being reckoned from the instant of closing the circuit; p stands for 2π times the periodicity, and $\theta = \text{arc} \tan \frac{pL}{r}$.

From (2) we see that the current is the sum of two terms, one of which is a pure harmonic function of the time, while the other is an exponential function, which becomes vanishingly small after a certain number of waves.

If $a = \theta$, the exponential term vanishes, and nothing abnormal happens at the instant of switching on. If a is greater or less than θ, the first few waves are not simple harmonic waves, but harmonic waves distorted by the addition of an exponential term. Since the simple harmonic component of the current alternates in sign, and the exponential component is always of the same sign, it is obvious that if $\theta > a$; *i.e.*, if the exponential function is positive, the effect is to increase the ordinates of the positive half-waves, and to reduce the ordinates of the positive half-waves, and to diminish the ordinates of the negative half-waves. The reverse of this happens if $a > \theta$.

We thus see that the sudden application of a simple harmonic E.M.F. to an inductive circuit of constant permeability will in general result in the phenomenon of "current-rushes." These current-rushes will be as great as possible when the distorting term is as great as possible, and this happens when $a = 0$; *i.e.*, when the switch is closed at the instant when the E.M.F. is passing through its zero value. The equation (2) then takes the form

$$i = \frac{E}{\sqrt{r^2 + p^2 L^2}} (\sin \overline{pt - \theta} + e^{-\frac{rt}{L}} \sin \theta). \quad (3)$$

§ 5. Any function which is capable of being represented as the sum of two simpler functions is most conveniently plotted by drawing the graphs of the component functions, and adding their ordinates. Now, if the resultant function has turning-values, it is obvious that the greatest maximum reached by the function can never exceed the sum of the greatest maxima of the component functions. In the case under consideration the current is the sum of two terms, a simple harmonic and an exponential term. Now the greatest value of the former is $\frac{E}{\sqrt{r^2+p^2L^2}}$, and the greatest value of the latter is $\frac{E}{\sqrt{r^2+p^2L^2}} \sin (\theta - a)$, or $\frac{E}{\sqrt{r^2+p^2L^2}} \sin \theta$ if $a = 0$. The current can therefore never exceed the value

$$\frac{E}{\sqrt{r^2+p^2L^2}} (1 + \sin \theta),$$

which is tantamount to saying that the "current-rush" as defined in § 3 must always be less than 2.

§ 6. It was thought desirable to confirm these theoretical conclusions by experiment. So far as the writer is aware, no attempt has hitherto been made to furnish direct experimental evidence of the existence of these current-rushes. But by means of the special switching arrangement mentioned above, and the apparatus shown in Fig. 1 and described in § 2, it is easy to obtain the actual shape of the current-curves, both normal and abnormal. In order to convince any non-mathematical reader of these articles that the exponential term occurring in the current equation is not a pleasant mathematical fiction, but a solid physical reality, we shall first work out and plot the theoretical curve for a special case, and then give the actual curve as determined by experiment.

(To be continued.)

SYNCHRONISING CLOCKS FOR ELECTRIC METERS.

BY J. W. JONES.

In electric meters of the Aron type, in which the current to be measured produces a difference in rate between two clocks (this difference being proportional to the amount of energy passed through), it is necessary that when no current is flowing the clocks should maintain the same rate, otherwise the difference will be registered as though caused by a current. This has always been a source of difficulty, and its importance may be gathered from the fact that, in a 100-ampere meter, having a constant of 0·5 for units, *i.e.*, each division on the top dial being equivalent to half a unit, an error in synchronism of one division per day would make a difference of 45 units in the quarter's account.

The writer, while in charge of the meter-testing department of the Westminster Electric Supply Corporation (Limited), has, during the last three years, experimented on various forms of synchronisers, and as provision had to be made for a large number of existing meters, it was a necessary condition that

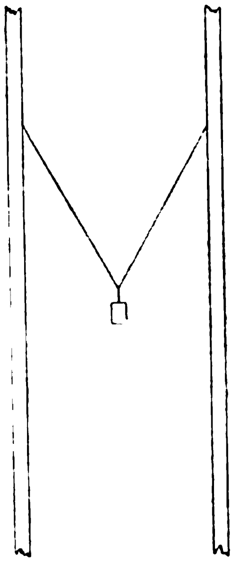

Fig. 1.

any improvement in this direction should not be made at the expense of much alteration; for this reason some types, which would probably have worked well, were not considered.

The first arrangement tried was that shown in Fig. 1, the pendulums being connected together by a loop of silk having a small weight at its centre; the result of this is that as one tends to go faster it is retarded, while the other is accelerated by an equal amount, they will therefore swing together unless the tendency to differ exceeds the amount for which the apparatus is adjusted.

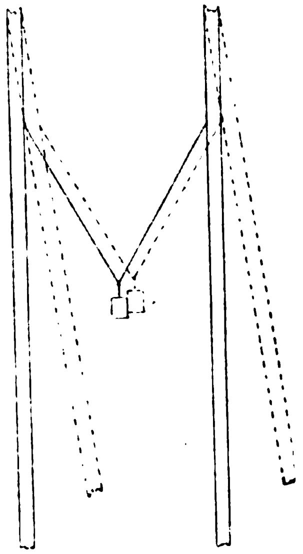

Fig. 2.

One evident objection to this form of synchroniser is that the clocks have to carry the extra weight at a point where there is least power, and as the pendulums approach the end of their swing, their momentum gradually falling off, they become more susceptible to any retarding influence; but as the weight is at the same time approaching its highest point (Fig. 2), and consequently increasing its effect, the pallet is sometimes found to miss one of the escapement teeth, and when this happens the pendulum seldom recovers, especially when

Digitized by Google

it is due to the sudden check experienced when a comparatively large current is switched off. Several modifications were made with the object of reducing the effect of the weights at end of swing, but all were found more or less uncertain.

The type at present in use, as will be seen from Fig. 3, consists of two very light magnets, A, B, fixed to the pendulums C, D, and then set so that their free ends lie behind one another at a distance of about ¼in. (Fig. 4). The attraction between the

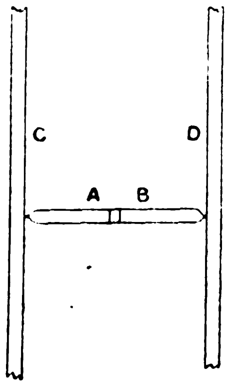

Fig. 3.

magnets has somewhat the same effect as the weights, but their weight, being so small, can have little or no influence on the clocks, while the increased pull at the end of swing is considerably diminished, as the free poles commence receding from one another soon after passing the centre, at, or near, which point lies the maximum effect (Figs. 3, 5, 6, 7); the action of the magnets being very smooth, the jerk noticed in the case of weights is hardly perceptible.

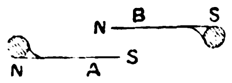

Fig. 4.

The objection to the magnets losing their power is not likely to be serious, if they are kept for some time before sending out.

The constant (*i.e.*, the figure by which the reading on the dials is multiplied to convert it into units) being found by passing a given number of units through the meter and

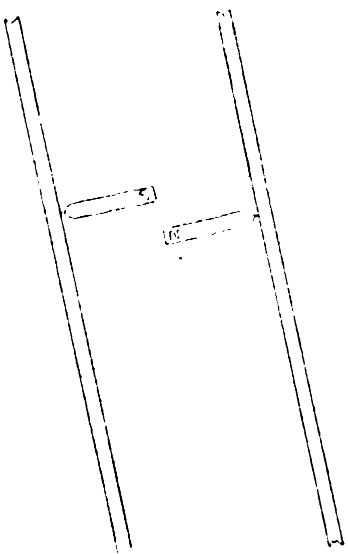

Fig. 5.

dividing by the number of divisions advanced, it is evident that if from any cause the advance for the same number of units falls off the constant will rise. The effect of any auxiliary system of synchronism would probably tend to raise the constant more as the load falls (the curves of Aron meters with permanent magnets on the pendulums generally have a slight tendency to rise at low loads independently of the state of synchronism); in this case, however, as will be seen from

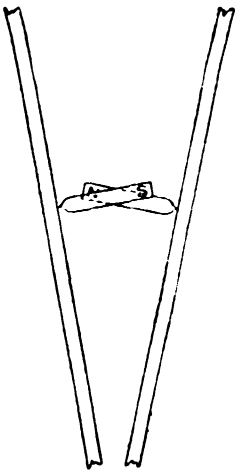

Fig. 6.

curves (Fig. 8) which are plotted from actual tests, and are representative of results now frequently met with in ordinary work,

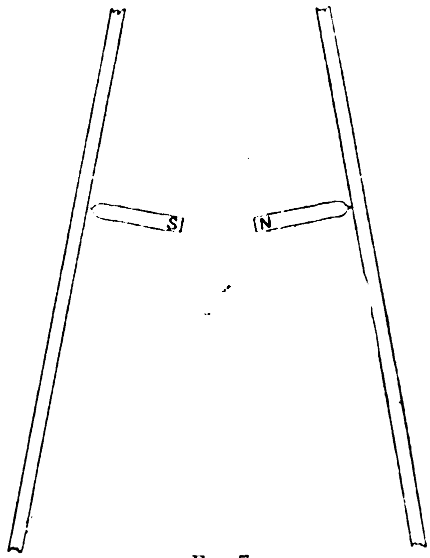

Fig. 7.

the constant seems to keep well to the horizontal until the load drops to between 1 and 3 per cent. of the maximum—in

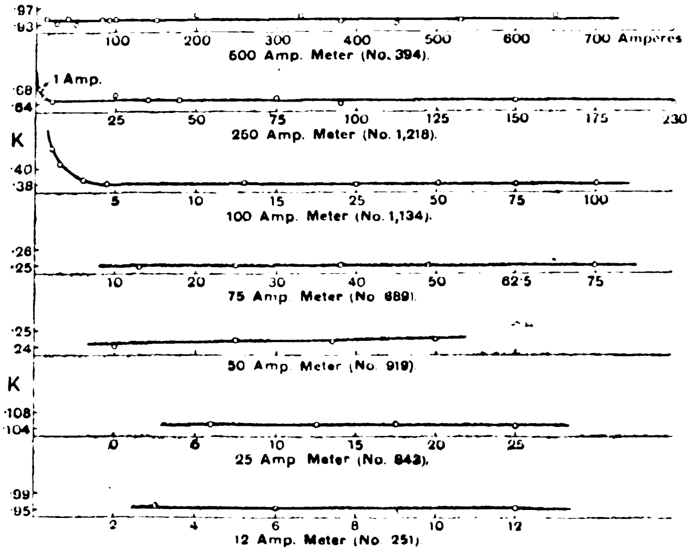

Fig. 8.

these tests (Fig. 8) the range of synchronism was not ascertained, but would probably have been about three divisions per day, which is found to be a convenient amount for usual working

Digitized by Google

conditions—at which point it rises somewhat abruptly. This is, of course, a loss to the Supply Company; but if the capacity of meter is selected with due regard to the probable average load, the amount of energy it should register at this point will be comparatively small, and an error of 5 or even 10 per cent. will not be a serious matter.

As it is impossible to tell beforehand in which direction the clocks are likely to change, it is obvious that the best position for the regulating nut on the standard pendulum will be mid-way between the extreme points, to which it would have to be moved to make the clocks go backward or forward against the effect of the synchroniser; should it be at a point between the true zero and one limit, the range of synchroniser in that direction would be less, while for the other direction it would be correspondingly greater.

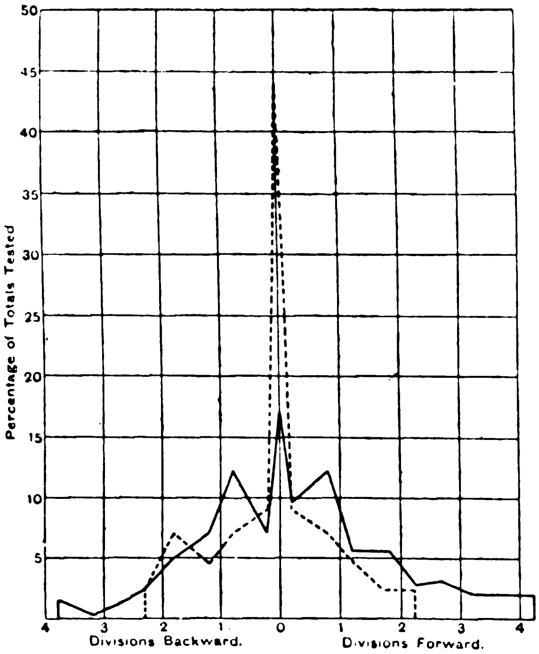

FIG. 9.—Dotted lines, Meters with Magnets. Total 43. Thick lines, Meters without Synchronisers. Total 250.

Within the last 18 months certain meters were for various reasons suspected of being out of time, of these 43 had magnets fitted, while 250 had no synchronisers of any kind. The results of these tests shown in the curves (Fig. 9) cannot of course be considered as representative of the true state of all meters on circuit, and are only given to show the results as far as the experiments have gone. The number at present fitted is about 700.

A CONTRIBUTION TO THE THEORY OF TELEPHONY.

BY A. E. KENNELLY.

The theory of the transmission of telephonic current-waves is complex to the degree that the wave character of their generated E.M.F. must be, in order to follow, and even partly conserve, the highly composite character of vocal vibrations in air. Nevertheless, the theory of transmitting sinusoidal current waves of any single frequency within telephonic range is simple, and with judiciously selected values of frequency and amplitude the application of this elementary theory may, with due reservation, be of practical value.

It is the object of this article to develop the theory of simple harmonic telephony in its simplest form, and to point out a few of the consequences.

A B in Fig. 1 represents a single line of copper wire, L miles or kilometres in length, with an induction coil transmitter at A, a receiving telephone at B, and ground return circuit.

If we assume that a pure musical note of some standard frequency is sung steadily before the transmitter at A, producing a steady sinusoidal current in the primary circuit of the coil, a sinusoidal E.M.F. will be generated in the secondary winding. The E.M.F. delivered at the terminal A will, however, depend upon the load, namely; the impedance of the line and receiving instrument.

The manner in which the voltage of delivery varies with the load may be observed by experimentally substituting for the line an adjustable non-inductive resistance, and measuring the E.M.F. at terminals with a delicate electrostatic volt-

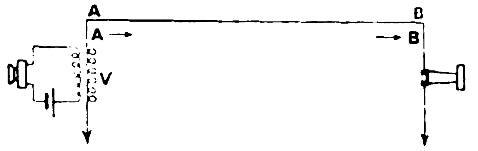

FIG. 1.

meter as this resistance is changed. The following table and curve (Fig. 2) gives the result of a series of observations made with a small telephone induction coil of European construction, having a primary of 1·21 Ω and 0·0091 H, a secondary of 393 Ω and 1·13 H, and a mutual inductance of 0·12 H, with two storage cells in the primary circuit, and the note "middle c" of 256∿ sustained in a moderately loud voice before the transmitter. The readings were too variable to admit of a high

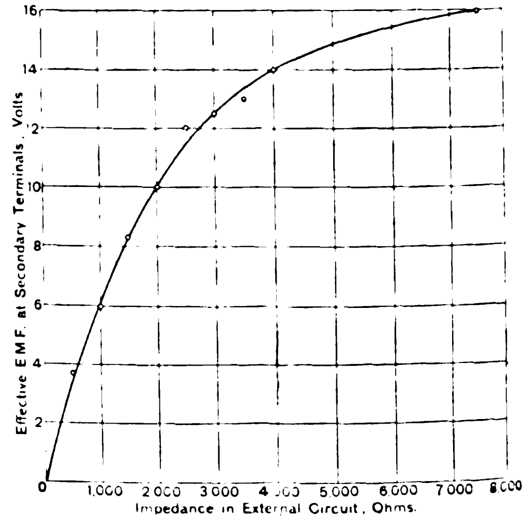

FIG. 2.—Curves Representing the Observed Relation of Effective Terminal E.M.F. to Load in a Telephone Induction Coil.

degree of accuracy, but the curve fairly represents the terminal E.M.F. produced by the transmitting apparatus under those conditions for any external impedance up to 7,500 ohms:

Ext Res.	Effective volts at terminals.
500	3·75
1,000	6·0
1,500	8·25
2,000	10·0
2,500	12·0
3,000	12·5
3,500	13·0
4,000	14·0
7,500	16·0

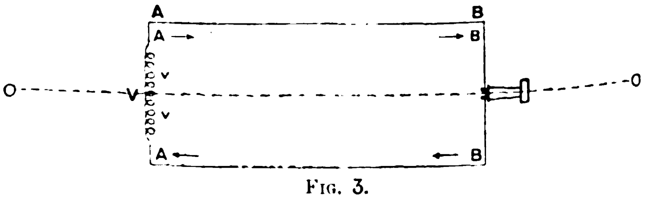

FIG. 3.

Returning, then, to Fig. 1, the effective voltage at the terminal A is experimentally determinable when the impedance of the line and receiving instrument can be assigned.

The distance at which simple harmonic sound waves will be recognisable with sufficient clearness for the purposes of intelligent communication will then depend upon the strength of the current reaching the telephone at B, the usual amount of "cross-talk" and other disturbances being taken into consideration.

Digitized by Google

The problem may therefore be stated as follows:—For any given homogeneous line of known resistance, inductance, leakage, and capacity, grounding through apparatus of known impedance, to find the total impedance as presented at A; and thence, having determined the effective pressure at A, to find the current strength that will reach B. Simple harmonic telephony will then be practicable or not according as this current strength exceeds or falls short of some experimentally determined value at the standard frequency adopted.

Let L be the length of the line in miles or kilometres.
- r „ its conductor resistance in ohms per mile or kilo.
- l „ its inductance in henrys per mile or kilometre.
- c „ its capacity in farads per mile or kilometre.
- g „ its leakage conductance in mhos per mile or kilo.
- ω „ $2\pi\times$ the frequency.
- j „ $\sqrt{-1}$.
- e „ the effective terminal voltage at A.
- i „ the current strength through B, effective amperes.
- I „ the effective current strength at A in amperes.
- J „ the vector impedance of the apparatus at B.

But long distance telephony employs metallic circuits, such as is represented in Fig. 3, with an effective E.M.F. E. The line O O divides this circuit into two symmetrical halves, each as though employing ground return, and with half the E.M.F. at A, half the impedance in the apparatus at B, and twice the capacity allowed to each wire that is measured between them when insulated from the ground and from each other. In equation (1) we therefore insert half the vector quantity J, and the quotient e/I then gives the impedance of either half of the complete circuit. Twice this result, being the impedance of the loop at A, E, is obtained from the data, and e, or half of E inserted in (2) or (5), supplies the strength of received current i.

We may now consider some examples of these formulæ.

First Case.—Two parallel overhead wires, each 950 miles long, of hard-drawn copper 0·165″ (0·419 cm.) in diameter, are supported on poles at an interaxial distance of 9″ (22·9 cms.), no other wires being in their vicinity. Then each will have per mile a resistance of 2·2 ohms, a capacity of $0{\cdot}009525\times10^{-6}$ farad, an inductance of 0·00159 henry, and a leakage con-

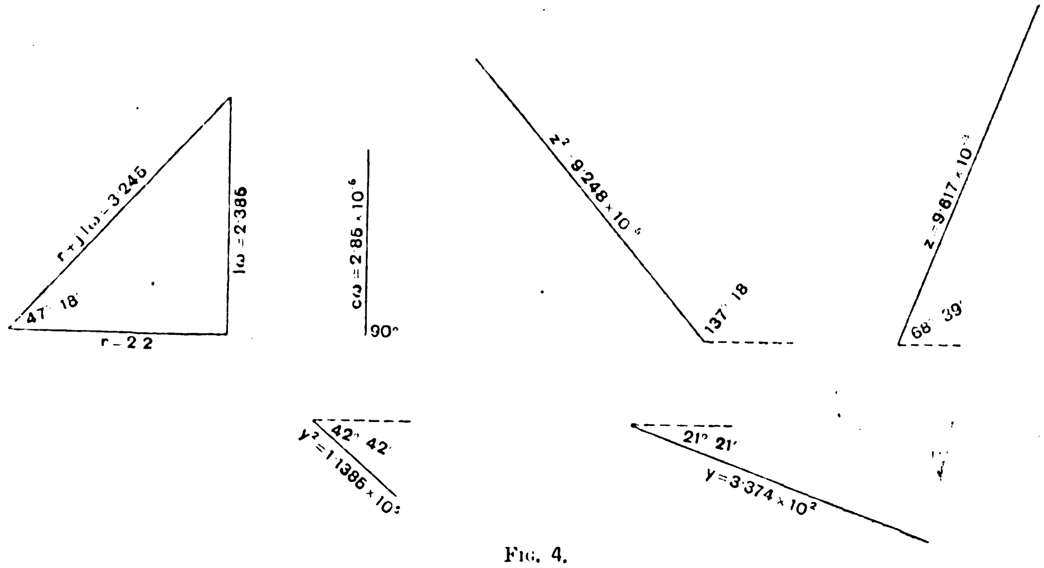

Fig. 4.

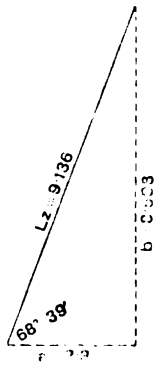

Fig. 5.

J will usually have the form $(\mathrm{R_T}+j\,\mathrm{L_T}\,\omega)$, where $\mathrm{R_T}$ and $\mathrm{L_T}$ are the resistance and inductance of the apparatus.

Then it can be readily shown that

$$\mathrm{I}=\frac{e}{y\sinh \mathrm{L}z}\left(\cosh \mathrm{L}z-\frac{\mathrm{J}}{y\sinh \mathrm{L}z+\mathrm{J}\cosh \mathrm{L}z}\right), \quad . \quad (1)$$

and

$$i=\frac{e}{y\sinh \mathrm{L}z+\mathrm{J}\cosh \mathrm{L}z}, \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where $z=\sqrt{(r+jl\omega)(g+jc\omega)}$ and $y=\sqrt{\dfrac{r+jl\omega}{g+jc\omega}}$. . (3)

These equations give the magnitude and phase of the currents at the receiving and transmitting ends of the line, the quotient e/I in (1) being, of course, the impedance of the line at A, which, being computed, gives both e and I, whence equation (2) determines the serviceability of the line.

These equations involve plane vectors, of which the rules for treatment are given in the *Electrical World* for January 6, 1894, Vol. XXIII., No. 1, p. 18. The equations may, however, be further simplified when dealing with electrically long lines—that is to say, lines approaching the limitations of transmission—for in such cases the influence of impedance in the receiving apparatus usually ceases to be significant upon the circuit, and we may make $\mathrm{J}=0$; while, since the vector L z is then sure to be more than two units in length, its hyperbolic tangent in (1) will be practically unity, so that for long lines here considered our equations become:—

$$\mathrm{I}=\frac{e}{y\tanh \mathrm{L}z}=\frac{e}{y}, \quad . \quad . \quad . \quad . \quad . \quad (4)$$

$$\text{and } i=\frac{e}{y\sinh \mathrm{L}z}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

ductance quite negligible. Then if the simple harmonic standard frequency is 238·7 ∾ making $\omega=1{,}500$, we have

$$\mathrm{L}=950$$
$$r=2{\cdot}2$$
$$l=1{\cdot}59\times10^{-3}=\therefore l\omega\ 2{\cdot}385$$
$$\text{(doubled) } c=1{\cdot}9\ \times10^{-8}\therefore c\omega=2\cdot85\times10^{-5}$$
$$g=0$$

Therefore, as shown in Fig. 4, $z^2=9{\cdot}248\times10^{-5}\diagdown 137^\circ.18'$

$z=9{\cdot}617\times10^{-3}\ \angle 68^\circ.39'$, $y^2=1{\cdot}1385\times10^{5}\ \diagdown 42^\circ.42'$,

$y=3{\cdot}374\times10^{2}\diagdown 21^\circ.21'$

It is to be observed that twice the actual value of c has to be allowed owing to considering the lines as being operated independently with ground return. Similar remarks apply to the case on page 19, *Electrical World*, Vol. XXIII. The impedance y of one line is thus 337 ohms, and 674 ohms is the impedance of the loop at A. By reference to Fig. 1, it appears that the terminal pressure which the transmitter would support on this circuit would be 4·6 volts, or 2·3 volts on each wire. Fig. 5 shows L z, which is L times the length of the vector z, and with components a and jb of 3·326 and 8·508 respectively. The hyperbolic sine may be fully worked out as indicated on page 18, *Electrical World*, Vol. XXIII.; but whenever, as in this instance, the horizontal component a is greater than 2, the maximum possible error in the numerical value of sinh L z made by ignoring the vertical component and the phase is 3·5 per cent., and when a is greater than 2·5, 1·25 per cent., rapidly dwindling. We may, therefore, when considering long lines, write equation (5) as

$$i=\frac{e}{y\sinh a} \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

Digitized by Google

Here $\sinh a = 13{\cdot}9$, and $i = \dfrac{2 \cdot 3}{337 \times 13 \cdot 9} = 0{\cdot}0004905$ ampere.

This is the current strength we should expect at B.

Second Case.—The same wires separated to an interaxial distance of 72″ (183 cms.), the inductance per mile of each is now 0·002259H, and the capacity of each to each insulated $0{\cdot}01321 \times 10^{-6}$ farad. Thus, $l\omega = 3{\cdot}389$, and doubled $c\omega$ $1{\cdot}981 \times 10^{-5}$. Fig. 6 represents the corresponding steps in computation $z^2 = 8{\cdot}00 \times 10^{-5} \backslash 147^\circ.1'$, $z = 8{\cdot}944 \times 10^{-3}$ $/73^\circ.30'.30''$, $Lz = 8{\cdot}498 / 73^\circ.30'.30''$, $y^2 = 2{\cdot}041 \times 10^5 \backslash 32^\circ.59'$ $y = 4{\cdot}518 \times 10^2 \backslash 16^\circ.29'.30''$.

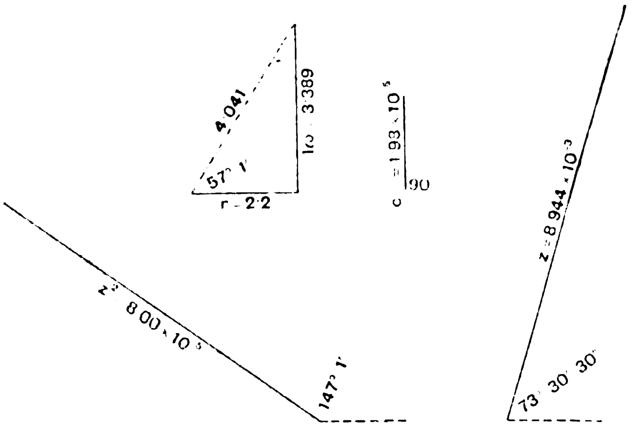

Fig. 6.

The impedance of the loop at A or $2y$ is now 904 ohms, at which the terminal pressure is E = 6 volts, or three to each wire. Entering equation (6) with this value of e, Fig. 7 shows that the horizontal component of Lz is now 2·412, whose hyperbolic sine is 5·53. The received current is consequently $\dfrac{3}{452 \times 5{\cdot}53} = 0{\cdot}0012$ ampere.

Increasing the distance between the wires from 9 to 72in. has more than doubled the strength of the current at B.

By watching the geometrical development of the computation, the utility of inductance in telephonic transmission is symbolically apparent in two ways. First by making the length $(r + jl\omega)$ greater, it adds to the length of y, and thus augments the impedance at A and the effective voltage delivered to the line. Secondly, it increases the angle of z and Lz, thus reducing the horizontal component a upon which the value of $\sinh a$ so sensitively depends. On the other hand, it will be evident that beyond a certain value the beneficial influence of inductance will cease.

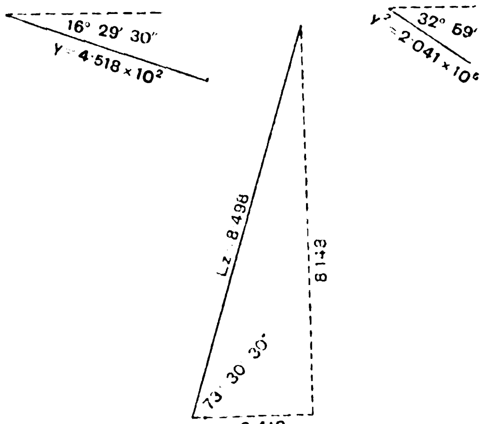

Fig. 7.

Equations (1) and (4) indicate that when the circuit is sufficiently long to make the horizontal component of Lz more than 2, the factor $\tanh Lz$ is practically unity, and the impedance of the circuit as apparent at the transmitter becomes constant, no matter how far the line be then extended. The effective voltage of delivery therefore remains constant, and the received current, as the length of line increases, depends entirely upon the reciprocal of $\sinh a$. In other words, with a moderately long line of fixed and uniform electrical constants, the strength of the received current varies inversely as the hyperbolic sine of a fraction of its length and not inversely as the square of its length. Fig. 8 gives the curve of hyberbolic sines, which may be employed when a table of this function is not available. The dotted line represents a particular curve of squares. The agreement between the two curves is very fair until the variable exceeds 3·5, and, to a first approximation, therefore, the law that assigns the amplitude of received current to the inverse square le of the length is correct. This does not, of course, contravene Lord Kelvin's law of signal transmission, which asserts that the interval of time required to bring the amplitude of continuous current strength received at the distant end of a cable (having small inductance in relation to its capacity), to a given fraction of the ultimate full maximum, varies as the square of the cable's length. In the case of harmonic telephony before us, we consider only the amplitude of harmonic current waves that have already practically reached their full development; and the progress of that development towards maturity, at the start, and in the initial stages of transmission, is removed from present consideration.

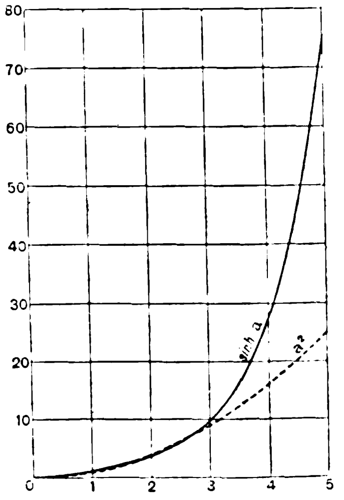

Fig. 8.—Curves of sinh a and a^2.

Third Case.—Two No. 10 A.W.G. copper wires, 0·1019″ (0·2588cm.) in diameter, are suspended parallel and alone upon poles, at an interaxial distance of 1ft. (30·48cm.). Assuming that their capacity when insulated from each other and from ground is 0·007 microfarads per mile, their separate inductances 2·138 millihenrys per mile, their resistances each 5·28 ohms, and their insulation each 250,000 ohms per mile, required the distance at which harmonic telephony will be possible with the special transmitter above referred to, when the limiting current strength at $\omega = 1{,}500$ is 0·00025 ampere.

Here $r = 5{\cdot}28$, $l = 2{\cdot}138 \times 10^{-3}$, doubled $c = 1{\cdot}4 \times 10^{-8}$, $g = 4 \times 10^{-6}$, $l\omega = 3{\cdot}207$, $c\omega = 2{\cdot}1 \times 10^{-5}$.

Constructing triangles as before, we find $(r + jl\omega) = 6{\cdot}178 \backslash 31^\circ.16'.30''$ and $(g + jc\omega) = 2{\cdot}138 \times 10^{-5} / 79^\circ.1'$. Whence $z = 0{\cdot}01149 / 55^\circ.8'.45''$., and $y = 537{\cdot}6$ with neglected phase. The loop impedance at A is 1,075 ohms, to which the transmitter will respond with a terminal E.M.F. of 6·7 volts by Fig. 1, or 3·35 volts to each wire. We have then the relation $e/(y \sinh a) = 0{\cdot}00025$, or $\sinh a = 24{\cdot}93$, so that $a = 3{\cdot}91$. Lz is $3{\cdot}91/\cos.55^\circ.8'.45''$, or 6·842, and $L = 6{\cdot}842 / 0{\cdot}01149 = 595$ miles. The harmonic sound reproduction would have the limiting amplitude at about 600 miles.

In conclusion, it may be pointed out that all the preceding formulæ apply immediately to continuous-current *leaky* circuits by suppressing the influence of their inductance and capacity; that is, by equating l and c to zero.

MODERN ELECTRO-CHEMICAL THEORY AND ITS BEARING UPON THE PRACTICE OF THE FUTURE.*

BY DR. OSTWALD.

The bulk of the benzol produced in England, amounting to many thousand gallons, is annually exported from the land of its origin to Germany. The significance of this fact is best grasped when it is considered that there is but little use for benzol as such, but that it serves for the preparation of other commodities such as colours, perfumes, and drugs. Benzol itself is indeed a semi-raw material, and its export in a partially-manufactured condition is clear proof that the oldest industrial country in the world is compelled to abandon the manufacture of merchantable products from coal tar at a point far short of that which is ultimately attained, thus foregoing the more remunerative part of their utilisation, and allowing the greater share of the profit which accrues to be secured by another nation. Seeing that the production of coal tar colours on a commercial scale was first achieved in England, the question naturally arises: How can the present industrial decadence, indicated by the shifting of trade adverted to above, have occurred? The answer is best to be found in the impressions conveyed to the author by a sojourn in this country.

He visited an industrial town of considerable importance and called upon the Professor of Chemistry at the local college. The laboratory, which was excellently fitted, was shown to him with obvious pride, but enquiry as to the number of students attending elicited the fact that there were but few. As a saving clause it was stated that the teacher of dyeing and calico-printing attached to the same institution, had five times as many students as the Professor of Chemistry. Far from being impressed by this fact the author immediately put his finger on the evil of the system thus exposed. The English student has too great a belief in the value of "practical" subjects to waste time in learning pure chemistry, and when wishing to become a technically trained dyer, learns dyeing instead of the chemical principles upon which dyeing depends. The natural result is that at the first notable departure from the art of dyeing as he learnt it, he is utterly at a loss, and has to begin learning new empirical methods instead of applying that general knowledge which the technical man who has studied chemistry before dyeing has fully acquired. The secret of German industrial success is this: Germans have grasped the fact that science is the best practice.

Electro-chemistry has been somewhat behindhand in the general development of technical knowledge, chiefly because electricians have been hitherto chiefly concerned in the evolution of purely mechanical appliances; a meeting place of science and electrical technology is provided by those electrolytic problems which are now of especial interest. The present time is well fitted for investigation of this kind. The century-old problem of the voltaic couple is in process of solution. We are now in the possession of sufficient knowledge to calculate the E.M.F. of a given couple with a high degree of approximation, and our information concerning electrical conduction is also considerable. The modern dissociation theory of solution must be invoked to provide a satisfactory explanation, and in this particular instance its electrical rather than its chemical aspect may be profitably considered. Taking the case of a dilute solution of sodium chloride in water—*e.g.*, 0·5grm. per litre—it is found that such a solution is a good conductor. Adopting the view that conduction depends on the translation of electrical charges by ions, it is clear that with sodium chloride of the strength given, sodium ions act as carriers of positive electricity and chlorine ions of negative electricity. This solution being dilute, the distance separating any given ion from another of the same kind is comparatively great, whence it follows that the period during which an ion—*e.g.*, of sodium—exists alone in the watery solution, is greater than that passed by it in the combined state. On grounds of the kind thus indicated, it becomes possible to calculate what fraction of a given electrolyte is split up into ions. The conditions determining the electrical conductivity of a solution admit of simple definition. In every electrolyte the conductivity is proportional to the number of ions per unit volume, and also to two constants—the velocities of migration of the ions differing in kind. This velocity is greatest in the case of hydrogen, whence it follows that acids are the best conductors in solution. The question of the conditions governing E.M.F. is, however, of still greater moment than that relating to conductivity, and may be dealt with in a similar manner.

The starting point for reasoning on this subject consists in a full appreciation of the nature of osmotic pressure, which may be stated thus: When a concentrated aqueous solution is covered by a layer of water, diffusion takes place until the concentration is uniform. The cause of movement from one layer to the other has the character of a pressure, and is termed osmotic pressure. To prove the existence of this pressure it is only necessary to oppose the movement of the dissolved substance, which can be done by interposing a septum between the two layers which is pervious to water but not to the substance in solution. A septum of this kind has been devised by Pfeffer,* and by its means osmotic pressure has been shown actually to exist, and to be of considerable magnitude. Thus a solution such as sea-water gives a pressure of about 20 atmospheres. The origin of this pressure is still unknown, but its existence is certain, and obtains for all soluble substances. By surrounding a solution with an osmotic septum strong enough to resist the pressure, a maximum osmotic pressure is obtained, which is dependent on the solubility of the substance in solution, and cannot be exceeded. This pressure is perfectly analogous to steam pressure, and just as steam pressure may be used to drive an engine, so can osmotic pressure be caused to drive a corresponding machine. *A galvanic cell is nothing more than a machine driven by osmotic pressure.*

In order to understand this fully, the process of solution which a metal undergoes when used in a galvanic cell must be studied somewhat closely. In an ordinary Daniell cell, zinc dissolves to form zinc sulphate; this, stated in dissociation language, means that zinc ions electrically charged are formed from the metal in the massive unelectrical condition. A corresponding number of copper ions are translated from their electrically-charged condition to that of the ordinary metal. At the zinc electrode positive electricity is continually received, and at the copper electrode it is given up. The conductive connection of the two electrodes determines the simultaneous occurrence of a chemical and an electrical change, neither of which takes place without the other. The analogy between pressure and E.M.F. is now complete. Just as an engine can be driven by means of two fluids of different pressure, so can an electrical cell be operated by two sources of different electrical pressure. The zinc and copper of a Daniell cell are two such sources, and the difference of their electrical pressure depends on the difference of osmotic pressure due to the zinc on one side and the copper on the other. The higher the pressure arising from the zinc and the lower that to be overcome at the copper electrode, the better the cell works and the greater is its E.M.F.

The pressure measuring the endeavour of a metal to go into solution, or the "solution-pressure," as it may be termed, is of perfectly definite magnitude for every metal, and it appears at first sight as if it simply depends on the nature of the metal in the cell and on no other factor. That there is another factor becomes apparent from the following considerations: When the zinc electrode is in contact with the solution, the effective solution pressure depends not only on the zinc but also on the zinc ions present in the solution which exercise a counter pressure. The excess of the first above the second is the effective solution-pressure. The E.M.F. due to the zinc is therefore the greater the smaller the counter-pressure of the ions, *i.e.*, the lower the concentration of the solution in respect of its content of zinc ions. As a matter of fact the E.M.F. of a Daniell cell is greater when sulphuric acid is in contact with the zinc than when zinc sulphate is used. The converse holds in the case of the copper electrode where it is desirable that the concentration of the liquid in respect of copper ions should be at its maximum, in order that the pressure exerted by those

* Zweite Jahres Versammlung des Verbandes der Electrotechniker Deutschlands in Leipzig am 7-9 Juin, 1894. *Electrotechnische Zeitschrift*, 1894, 24, pp. 329—331.

* The septum consists of the colloid cupric ferrocyanide.

Digitized by Google

ions may aid the deposition of copper in the ordinary metallic state. This, then, is a simple exposition, quantitative in character, comparable with the Newtonian law of gravitation of the theory of the galvanic cell. The theory gives definite conclusions for definite cases, and those instances in which complete calculation of results from data has not been effected probably arise not from imperfection of the theory, but rather from known mathematical difficulties. Certain constants have also yet to be determined.

The conditions under which the best output from a given cell may be obtained can now be ascertained. On the zinc side a minimum ion pressure must prevail. This is best secured by using a solution in which but few zinc ions are present, even when more or less zinc has been dissolved in it. This is not an impossible requirement, because the whole of a dissolved metal is not necessarily in the form of ions. From this point of view the use of *alkaline* liquids for the zinc (now frequently adopted) has especial significance. The next step consists in combining the use of an alkaline liquid for the zinc electrode with that of an acid liquid at the cathode, in order to obtain the greatest possible E.M.F. It is a consequence of the theory already expounded that the oxidising agent will act better in an acid liquid, and the reducing agent in an alkaline liquid. Thus, a cell consisting of zinc in caustic potash and carbon in strong nitric acid has an E.M.F. of more than 2·5 volts. Whether it is possible to make such a cell practically available is a question to which it would be premature to reply.

The matters touched upon above become of insignificant importance when compared with a much larger problem, the solution of which must be looked for from the electro-chemist. The low efficiency of the steam engine, as a means for the conversion of the chemical energy of fuel is not sufficiently widely recognised. In the best cases not more than 10 per cent. appears as mechanical work. Now, it may be admitted that the complete conversion of heat into mechanical work cannot be attained; but it is possible to calculate the fraction which can be obtained from a given quantity of heat at a given temperature on allowing the temperature to fall through a known range, and on taking this as a basis it is found that only about one-seventh of the total convertible amount is utilised. The steam engine, regarded as a machine, is not responsible for this state of things, which depends far more on the fact that of the high temperature of the burning fuel (much understated at 1,000°C.) only a small portion is used, namely, that represented by the difference in temperature between the boiler and the condenser. The very large difference of temperature between the furnace and the boiler is not rendered available, and an improvement of the thermo-dynamic machine can only be rendered possible by the use of a higher initial temperature.

But the thermo-dynamic machine is not the only apparatus for the conversion of chemical energy into mechanical work. Should it be possible to obtain the energy of fuel in such a manner that heat as an intermediary was abolished, the difficulty of having to deal with high temperatures would be overcome and the whole quantity of energy obtained without encountering that inconvenience. The way in which this, the most weighty of all technical questions, can be decided, must be shown by electro-chemistry. Had we a cell in which electrical energy was produced by the direct oxidation of carbon with an output approaching the theoretical, we should be on the brink of an industrial revolution compared with which the invention of the steam engine sinks into insignificance. It is not practicable to foretell the arrangement of a cell of this order, but one point may be insisted on which has been constantly ignored. The energy of a galvanic cell indubitably results from the chemical energy of its components, but complete conversion never occurs. What, then, are the conditions which permit of the maximum efficiency of conversion? The answer is that only *indirect* chemical reactions are electrically useful. The following experiment, therefore, acquires much significance. Two beakers connected by a filled syphon, contain a solution of potassium sulphate. In one is a rod of zinc, in the other one of platinum. On connecting these electrodes with a galvanometer a momentary current passes, and then the needle quickly comes to rest. This, of course, is due to polarisation, and in order to obtain a continued current, an acid liquid must be substituted for the original neutral solutions. The question now arises: To which beaker shall an acid (*e.g.*, sulphuric acid) be added? When this is put to most people, the reply is: "To the beaker containing the zinc." Actual trial shows, however, that no effect is thus produced, whereas when the acid is added to the liquid in the beaker containing the platinum the galvanometer needle flies to the stop. The apparently paradoxical result is obtained, that the acid must be placed in contact with the metal on which it has no action. This principle is perfectly general in character, and has been demonstrated to hold good in numerous cases. Its necessity is obvious on closer inspection. In order that the zinc may dissolve, ions must be formed, and receive their charge of positive electricity. That this may be possible it is requisite that the solution should give up a corresponding amount of positive electricity, *i.e.*, that an equivalent quantity of hydrogen must cease to be in the ion state, and must become converted into hydrogen gas. This giving up of positive electricity from the liquid cannot take place at the point where the zinc dissolves, because the contrary electrical change occurs there. It is therefore only possible for the hydrogen to come off at the cathode, as is actually the case.

It now becomes clear how fallacious was the method by which Jablochkoff sought to obtain electrical energy direct from carbon. He placed the carbon in fused nitre, and by its vigorous oxidation obtained a current so feeble that its utilisation was not to be thought of. The reason for this failure is as follows: The nitre should not be in contact with the oxidisable electrode, but with the electrode which is not attacked by oxidising substances. A parallel is found in the Bunsen cell where the oxidising substance (nitric acid) is not placed in contact with the substance to be oxidised (zinc), but with that upon which it has no action (carbon, which is unattacked under these conditions). Similarly the cell of the future (in which carbon is oxidised for the conversion of chemical into electrical energy) will have the oxidising material *at the point where the carbon to be oxidised is not.* Such a cell will exhibit exactly the same chemical processes as an ordinary furnace. On one side the carbon will be shovelled in, and on the other oxygen will be admitted, and the product of their indirect interaction will be CO_2. The one essential is a suitable electrolyte to interpose between the carbon and the oxygen, and permit of the occurrence of the electrical interactions, itself suffering no permanent change.

Another problem which will be grappled with in the future by the electro-chemist, is that of the storage of electrical energy by means of secondary cells. The energy stored in a cell is proportional to the quantity that remains in it and to the E.M.F. of the cell. The first is, in its turn, proportional to the electro-chemical equivalent of the material used. This, in the case of a lead accumulator is undesirably great, viz., 103·5. If aluminium, with an electro-chemical equivalent of 9, were available, the weight of the electrodes would be at once reduced to less than $\frac{1}{11}$ of their present amount. It is unlikely that aluminium will prove a practicable substitute, but it is not the only metal with a low electro-chemical equivalent, and something may be achieved by keeping this fact in view.

In conclusion the nature of electrolytic changes may be profitably considered. A conventional distinction between primary and secondary electrolytic changes has sprung up; but it is of little value and, indeed, scarcely tenable. On electrolysing a solution of potassium sulphate the products are not the ions K and SO_4, but hydrogen and caustic potash at the cathode, and oxygen and sulphuric acid at the anode, and these are often called secondary products on the assumption that K and SO_4 are first separated, and immediately act upon the water present, with the result that the substances mentioned above are obtained. But on measuring the E.M.F., which is necessary for this electrolysis, it is found to be smaller than that which would be necessary were it true that the change takes place in the manner conventionally received. The E.M.F. is, in actual fact, of the magnitude demanded by the production of the substances appearing at the anode and the cathode, on the assumption that they are not secondary, but are primary products. The principle is perfectly general; the E.M.F. is constantly dependent only on those reactions

Digitized by Google

which actually take place, and is in no way influenced by those arbitrarily termed primary. The distinction between primary and secondary products is therefore of little utility. There is, however, a distinction which is not commonly insisted upon as clearly as is desirable. It is that existing between the substances which are the intermediaries of conduction, and those which separate at the electrodes. They are not necessarily identical and can, indeed, be identical only in a few instances, for only a few ions are capable of passing over into the non-electrical condition without chemical change, as they must if the electrolysis should yield only primary products (using the phrase in its conventional sense).

The distinction which can properly be drawn between primary and secondary products of electrolytic decomposition is foreshadowed by the inquiry: What conducts the current, and what appears at the electrodes? In a few cases the two classes of substances are identical; as, for example, in the electrolysis of fused magnesium chloride, where chlorine and magnesium are evolved; in most instances, on the other hand, wholly different substances appear, and there is no necessity that they should be identical. When such choice of electrolytic products is possible, those substances are always produced whose separation requires a minimum E.M.F. It is wholly indifferent whether they are "primary" or "secondary," *i.e.*, whether they are concerned with the chief part of the conductivity of the electrolyte or not. All the ions present in an electrolyte, each acting according to its number (concentration), and its velocity of migration, come into play in the conduction of the current; for the polarisation at the electrodes only the final products of electrolysis have to be regarded. The two things are wholly independent. The matter, though but little regarded, is not of merely theoretical interest, for many errors of practical importance can be traced to want of appreciation of its cogency. In spite of the clearness with which many technical questions can be regarded in the light of scientific investigation, it must not be supposed that the labour of the technical inventor is rendered superfluous. Technical questions must be propounded before they can be answered, and even then the answer may not be forthcoming. The stimulus supplied by such problems is a "valuable consideration" for the help given in response to questions which admit of immediate solution.

MEETING OF THE ASSOCIATION OF MUNICIPAL ENGINEERS.

At the meeting of the Incorporated Association of Municipal and Country Engineers at the Institution of Civil Engineers, Westminster, on Friday last, Mr. J. N. Shoolbred, of London, read a Paper on the Bradford Corporation Electricity Supply, with the results of four years' works. The author pointed out the successful working of the installation at Bradford, the profits which have been made by the Corporation in addition to the provision of interest on capital and sinking fund, and the low working cost of the system, which compares favourably with any other in the kingdom. Mr. Robert Hammond contributed a paper on Electric Street Tramways. He gave a detailed description of the electric tramways at Buda-Pesth, which he inspected last year, and pointed out that there are at the present time in Europe 47 electric lines in operation, the total length being 194½ miles, and the horse-power employed 14,579. In the United States, however, where electric traction had reached its greatest development, 12,369 miles and 39,178 cars were in operation.

Having briefly reviewed the distinguishing characteristics of the accumulator, overhead and conduit systems, Mr. Hammond said the combination of electric traction and electric lighting appeared to be a most beneficial one. At the opening of the day, when the trams started operation, there was no load upon the electricity works, and this absence of load practically continued until sunset. Here, then, was a most convenient use for plant other wise lying idle. In the case of electricity works specially confined to traction, the whole of the standing charges were debited to the cost of the car mile run; whereas, if worked in connection with electric lighting, only a portion of those charges would be debited. It must, however, be borne in mind that at one period of each evening the electric lighting load and the tram load would clash, and this had hitherto been considered a bar to the combination of the two works. The author fully admitted that the overlapping of the loads was a matter of great moment, but he was convinced that an economical arrangement could be arrived at. The accumulator system was that which lent itself most readily to the combined plan. Up till the moment of reaching the top load there was a margin of capacity in the plant for doing the work of charging the batteries, and from the moment the load began to fall off this margin of capacity was released. In the case of systems of direct supply it might still be possible to tide over the period of maximum electric lighting load by secondary batteries fixed in the station; which, charged during the day, could be used at the critical period to give out the electrical energy necessary to feed the motors on the cars. There was a third plan, which he had lately been considering, and which, indeed, might prove the most economical method of dealing with the over-lapping difficulty, viz., the horsing of the tramcars during the time of the top lighting load. By whatever means, however, the over-lapping load was coped with, it by no means presented an insuperable difficulty, and even though, comparatively speaking, it might not be dealt with economically, the advantages of the combination of traction and lighting in one works completely outweighed the disadvantages connected with the less economical running of the trams for a short time daily.

Mr. CROMPTON said the battle which had raged over the low pressure continuous system and the high pressure alternating system between the two bodies of electricians had been very puzzling to Corporation Committees who had investigated the electric lighting of towns. The Bradford Committee had been strongly attacked for not having adopted the high-pressure system, but the returns showed that if they had done so their working costs would have been considerably higher, and their works would not have been the financial success they were at present. He knew what he was saying was slightly controversial and might be contradicted, but in saying it he was one of a very strong army, which included Lord Kelvin, the late Dr. Werner von Siemens, Prof. Von Hefner Alteneck, of Berlin, and Prof. Kennedy, who probably advised more Corporations than any other man in England. Those who advocated the high-pressure system were able to show a smaller cost for plant; but this was more than counterbalanced by the higher working costs. He was in a peculiar position. He advised three of the largest companies in London on the low-pressure system, and he held three-fourths of the capital of a high-pressure system at Chelmsford. That installation was just turning the corner, whereas in other towns the turning of the corner had taken place some years ago. The four low-pressure companies in London were paying an average of 5 per cent. on their capital. On the other side there were only two Companies—those at Newcastle—which were paying any interest on their capital when invested in high-pressure plant. The case of Newcastle was easily explained from the exceptionally low cost of coal. With regard to Mr. Hammond's Paper he considered he had put a very moderate case before them in favour of municipalities taking up the driving of trams by electricity.

Mr. R. HAMMOND regretted that from the point of view of the Association Mr. Crompton could not deal with the subject of Municipal electricity works generally rather than lay before them a plea for any particular system. With regard to electric trams he was very pleased to hear from so close an observer as Mr. Crompton that he had not put his case as strong as he might have put it. The great argument he wanted to drive home was that in electricity supply works there were perforce a great many idle hours, and that there was a capacity in those works which might very well be used for tramway traction. He need hardly point out how markedly the cost would be decreased by an increase of output, and this was especially so when they increased the output by doubling the number of hours for duration of work.

PROPAGATION OF MAGNETISATION OF IRON AS EFFECTED BY THE ELECTRIC CURRENTS IN THE IRON.*

BY J. HOPKINSON AND E. WILSON.

Consider a solid, cylindrical electromagnet; it is well known that, in reversing the magnetising current, the induction does not instantly reverse, but a certain time elapses before it again attains its full value, that it reverses at a later time at the centre of the core than near its surface, and that the delay in reversal near the centre is due to the electric currents induced in the iron. The object of the present Paper is to investigate these effects.

The magnet experimented upon had a diameter of 4in., and formed a closed magnetic circuit. Through a part of its length the cylinder of 4in. diameter was formed of an iron core surrounded by two concentric closely-fitting tubes. Exploring coils of fine copper wire were bedded in the iron between the surfaces of the tubes. The currents induced in these exploring coils were observed when the current in the main coil of the magnet was reversed. These currents in some cases last for over half a minute.

Inferences can be drawn from these results as to the behaviour of other diameters than 4in. Comparing two cylinders of different diameters, similar events occur, but at times proportional to the squares of the diameters of the cylinders. From this consideration and the experiments, a judgment is formed as to the effects of local currents in the cores of transformers and of the armatures of dynamo machines.

The Electrician.

(The Oldest Electrical Journal, 1861—1878.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny

Editorial, Publishing, and Printing Offices :

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams :* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co."

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies :—

Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

"THE ELECTRICIAN" *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as an Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Price 12s. 6d., post free 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d. post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free. Also in German, 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free, 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

ELECTRIC MOTIVE POWER. By A. T. SNELL. [*In preparation.*

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

THE LONDON COUNTY COUNCIL CONFERENCES ON TRADE CLASSES.

Whatever may be the shortcomings of the London County Council in other directions, it must be admitted that its policy in regard to technical or, as we prefer to call it, trade education, a subject over which so many local authorities appear to have gone hopelessly astray, has been marked by both tact and good sense. In the first place, instead of proceeding on the orthodox lines, and handing over the duty of supervising the industrial education of the metropolis to a committee composed solely of its own members, it decided in February, 1893, to delegate its functions to a body tolerably representative of the various interests concerned, and containing 15 outside members out of a total of 35. And within the past few months the Technical Education Board so constituted has taken a step which is even more conducive to the furtherance of genuine technical education than the original departure of the County Council. "Who is he that darkeneth counsel without knowledge?" is a question to which the present-day reply might well be, "The average advocate of so-called technical education;" a state of things for which there could be no better remedy than the series of trade conferences organised by the Board, the second of which, attended by representatives of the engineering, shipbuilding and metal trades, was held in Spring-gardens on Wednesday last week. Technical education is an expression that has been dinned into our ears for the last 12 years, and has almost as vague a meaning as socialism or polarisation. The refined scientific lectures at the Guilds Central Technical Institute, and the research work carried on by third-year students in its laboratories, is called technical education; but, of course, it differs widely from the system of instruction under discussion. "Trade Classes" is the simple name given at Finsbury to this very valuable branch, and, unlike "secondary education," has the peculiar merit of saying what it means.

The remarks of the speakers at this Conference, a full report of which will be found in another column, were characterised, as is generally the case where the speakers are in

Digitized by Google

daily contact with hard facts, by a keen appreciation of the limitations and possible evils of technical training. To a London foreman engineer "it mattered little that a man had learned the differential calculus if he could file a key into a wheel only indifferently well. . . . Until the commercial element of time was introduced, technical education would be a snare." The main discussion, however, centred around the desirability of trade apprentices being afforded by law or general custom opportunities of attending day classes, of the instructors being practical workmen, of every technical class being in some manner in touch with "the union or trade it represented," of confining instruction to those actually engaged in the trade taught; the now academic question of the relative merits of the old apprentice system and the modern method of school or college training being quite rightly only lightly touched upon. As regards the first point it would certainly seem right that just in proportion as the fine old system of indentured methodically-taught apprentices falls into desuetude employers should afford reasonable opportunities to the rising generation to learn the fundamental principles underlying their craft, not in stuffy lecture-rooms at the end of a day's work, but whilst the mind is fresh and receptive. Of course, if this desirable end cannot be attained by other means, the inevitable short Act would probably effect what humanity and enlightened self-interest had failed to accomplish. The demand that technical instructors should be practical workmen is a natural and extremely plausible one. Nothing can be more baneful than that a teacher should be set to teach the principles of a trade of which he has no real practical experience. At the same time, apart from the fact that, as one speaker pointed out, the best teacher is not necessarily the best workman, it must be remembered a life-long absorption in minute detail is not altogether the best preparation for one who is required to have a broad view. The third point, about which there was absolute unanimity, is, like the second, extremely specious on first consideration. Trade classes, if they are to serve any useful purpose must obviously be in close touch with the trade concerned; but that they should be controlled by the trade-unions is a demand of a very different nature, and the pliant deference paid to this behest at the Conference last week emphasises one of the dangers to which the existing order of things is exposed. If the plenary inspiration of the greater number is to be tamely accepted as a democratic dogma, improvements in machinery and manufacturing processes will be restrained by a well-nigh irresistible force.

Up to the present industrial education, in as far as it is concerned with the turning-out of more talented and versatile workmen, has to a large extent missed its mark; and the demand which speaker after speaker put forward at the Conference, that trade classes should be restricted to men actually in the trade, is but just and reasonable, if those excluded are to be the amateurs, dabblers, and well-to-do youths who are so prominent, not only at the day, but at the evening classes of many of our technical colleges. But to press the point, as did Mr. Walker, of the Electrical Trades Union, to the extent of excluding *bonâ-fide* working men merely because they happen to nominally belong to a slightly different trade, is both selfish and short-sighted. Mr. Walker is wrath with the authorities of the Battersea Polytechnic because gas-fitters are allowed to attend the electrical classes. Only a few minutes previously another representative of the electrical trade was crying out like a sensible man against excessive "sectionising." Specialism, carried to the degree to which it is in most modern processes, is a decided evil; though under existing conditions it is, so far as one can see, a necessary evil. All those who wish well to society in general, and the working man in particular, should surely welcome every opportunity that is offered of combating this tendency to narrow each man's labour to some small mechanical day stint. For our own part, we should anticipate that an experienced house-carpenter or gas-fitter would, with a modicum of electrical knowledge, make an excellent wireman. The work would be better done, and the worker, with two strings to his bow instead of one, would be far more independent of the vicissitudes of trade than before—two results which contravene no known principles except those of the narrowest-minded trade-unionism.

MODERN VIEWS OF ELECTRO-CHEMISTRY.

A very remarkable paper, by Prof. Ostwald, slightly condensed from published reports in foreign journals, appears in another column. It is so full of suggestive matter that we would rather recommend its study as a whole than endeavour to give an account of its salient features—a task of much difficulty and of doubtful utility in a case where each noteworthy statement depends for its power of instruction on a lengthy chain of reasoning, leading gradually to a logical conclusion. Nevertheless, there are a few points at once of much moment and sufficient isolation to serve as texts for debate and, possibly, for criticism. The preamble of the paper is worthy of the closest attention, for it shows that our greatest commercial rivals—the Germans—are fully alive to the advantages which they possess on account of their greater technical knowledge as a nation, and are also perfectly aware of what gives them those advantages. It is lawful to learn of the enemy, and when he, in the person of a spokesman of the calibre of Prof. Ostwald, deliberately states it as his opinion that the way in which to acquire a knowledge of the technical part of any industry is to thoroughly learn the science on which the practice of the industry ultimately rests, and to avoid the futile attempt to acquire mere "technical training," regardless of previous true education, it would be fatuous on our part to ignore or belittle the pronouncement. The view that a sound education in a science should precede the attempt to learn the details of the corresponding art, is one which we thoroughly endorse; but we would add to it the rider that the right man to receive the double training should be first secured. It is only because we have, as a nation, been fortunate in possessing a sufficiency of the right men, men of some originality, purposeful and able to face difficulties due to novel conditions as they arise, that we have won and retained our present industrial place. A little extra knowledge and discipline, however, would not harm us.

The audience to which the paper was primarily addressed consisted of electricians rather than chemists, and was accordingly restricted as far as possible to the electrical aspect of the questions touched upon. The chemical side is so completely complementary that its discussion could scarcely be avoided, and in several places might have been profitably extended. The reference to osmotic pressure in general carried with it allusion to the obscurity of the origin of that pressure—a matter still craving settlement. Comparison with steam pressure is valid if a source of renewal of the pressure as work is done by its means be postulated; pressure alone is only one factor of energy. Thus the definition of a galvanic cell as a machine driven by osmotic pressure should be amended in the sense that "it is a machine driven by energy, of which osmotic pressure is one factor." The comparison of the osmotic theory of the galvanic cell and the Newtonian theory of gravitation is, perhaps, scarcely to be maintained as yet, in face of the many

Digitized by Google

difficulties in the way of explaining all cases from the osmotic standpoint. Prof. OSTWALD is inclined to lay stress on the mathematical obstacles in the way of solution of some points admittedly obscure; the mathematician should at least be heard in his own defence, when, perchance, he would complain of inadequate data.

The ingenious and significant experiment of exciting a zinc-platinum couple by putting the solvent for the zinc on the platinum side of the cell, involves a principle so obvious that those to whom Prof. OSTWALD propounded his conundrum must surely have been taken unawares when they failed to answer it. But it is well worth repetition if only to show the principle upon which the construction of a cell producing electrical energy by the direct oxidation of carbon should be based. All efforts in this direction, in addition to that cited in the Paper, have, we believe, failed to take account of the *modus operandi* of the ordinary aqueous cell.

The mention of an instance in which the nature of the ions conducting a current and that of the products appearing at each electrode is identical—as, for example, in the electrolysis of a fused halogen salt—is interesting; but it would have been of yet further interest if Prof. OSTWALD had formulated his views concerning the electrolysis of a *pure* fused salt. The combination of two bodies appears not to take place in the absence of a third, which should be an electrolyte. Conversely, the dissociation of a binary compound will not occur under the same conditions. But the existence of ions of a binary compound involves its partial dissociation. Whence it follows that if no third substance be present which allows of dissociation, no portion of the binary compound will exist in the ion state, and consequently electrolysis cannot be effected. A binary compound should, therefore, either conduct as a metal or be an insulator. A pure fused halogen salt fulfils the requirements of a substance of this character, and should not suffer electrolysis until a third substance—*e.g.*, some impurity—has been introduced. The extreme electrical resistance of pure water tends to support this view of the behaviour of a binary compound exposed to electrolysis.

THE "S.K.C." TWO-PHASE SYSTEM.*

For the past three years the Stanley Electric Manufacturing Company, of Pittsfield, Mass., has been perfecting a two-phased alternating current system for the distribution of light and power indiscriminately from the same generator and circuit at the highest commercial frequency. The objects kept in view by the inventors were, first, the production of a system which would permit of an economical and satisfactory service of both light and power from the same alternating generator and circuit, and one of such a character that existing light companies could operate it without discarding their present apparatus; second, a system which would make it possible for those just starting in the business to equip a station with one class of apparatus for all purposes, thus avoiding the multiplication of both circuits and apparatus necessary in the past when a company desired to furnish not only incandescent and arc lights, but power; third, to make possible the commercial transmission of water power over long distances and the distribution of the same for lighting and power by a simple system not requiring the duplication of apparatus and many conversions.

The various apparatus included in the system are the joint invention of Mr. William Stanley, Mr. John F. Kelly, and Mr. C. C. Chesney, and so closely have their labours been intertwined that the Company has adopted the three initials "S. K. C." as the distinguishing mark of the various devices included in the system. A great disadvantage of the alternating-current system of distribution as heretofore applied has resulted from its not being able to furnish power service from the same mains, and thus necessitating, where there is a demand for power service, the installation of direct-current machinery and a separate system of distribution. With the system here described a lighting company may very largely increase its earning capital by being able to instal motors on its lighting circuit. It is considered a safe statement to make, that in the majority of towns of any size more can be made by furnishing power than light, as the demands of the former are fairly steady for from eight to ten hours, whereas the maximum lighting service averages only three to four hours.

The inventors call attention to the fact that their two-phased generators can be used interchangeably with the present single-phased machines, and, in fact, fit in with existing systems just as well as new single-phased generators. By adding one of these generators to its present equipment, and by combining the two existing circuits at the station switchboard, or, at the worst, by adding one or two more small line wires, a station can be equipped for furnishing light and power indiscriminately, and when the hours of power service are heavy the two-phased machine can be

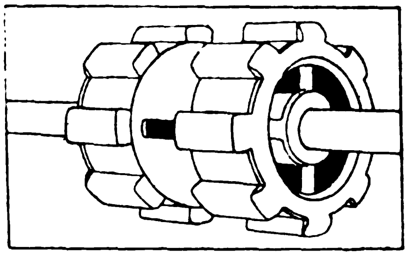

FIG. 1.—Two-Phase Inductor.

run on two or more ordinary two-wire single-phased circuits just as well as one or two of the old single-phased machines can be run on them. It is not necessary to throw anything away, as the present transformers and generators are just as good and useful with the proposed system as with the original ones.

Stress is laid upon the important element in this system, that as motors are started and stopped, or their loads increased or decreased, lights on the same circuit are not perceptibly influenced; also upon the fact that this system can be used with the highest frequencies, thus securing the great advantages possessed by high over low frequencies in first cost, superior regulation, and economy of operation of transformers.

The generators are all of the same electrical design; but have, however, a somewhat different mechanical structure in the larger and smaller types. The revolving part of this machine, which is shown in Fig. 1, is really the field; but is more properly termed

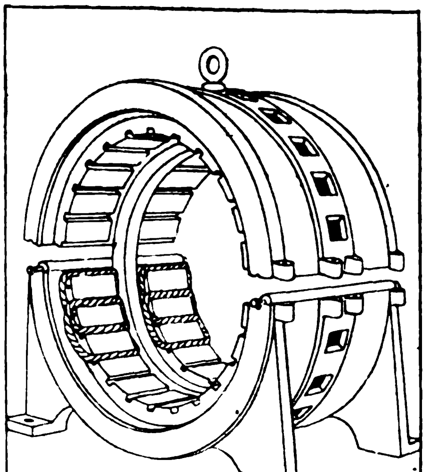

FIG. 2.—Armature of Two-Phase Generator.

the inductor. This is made of a steel casting, upon the periphery of which polar projections of iron laminæ are securely fastened. There is no wire whatever on this inductor, and consequently trouble is obviated from band wires, insulation and collectors, it being simply a mass of metal which can be put in place and revolved with a feeling of perfert certainty that nothing can happen to it.

The armature shown in Fig. 2 is made up of laminæ of iron, and is stationary, constituting, in fact, the body of the machine. The individual coils are very small, are wound separately on forms, and then secured in grooves provided for them in the laminations. Being so small and stationary, it is a comparatively simple matter to insulate them to safely withstand E.M.F.'s which would not be at all safe to generate in the older types of alternating machines. If a coil should be destroyed by lightning or any other cause, it can be readily replaced by the ordinary men employed about a

* Abstract from the *Electrical World* of New York.

Digitized by Google

station, as can be seen by reference to the cut. In the small machines it is only necessary to take off the top half of the bearings, lift off the top part of the armature and raise the inductor, when all the coils are easily accessible. In the machine of 240 kilowatt capacity and larger the great weight of the parts would make this plan very inconvenient in many stations, so removable side tables are furnished with this type and, by turning hand screws on each side, the machine can be drawn apart and all the armature coils exposed and made easily accessible. This does not require disturbing the inductor at all, which when the machine is opened simply hangs in its place in the bearings. The side tables need not be kept in place except when needed, as they are removable.

The armature and field wires are brought out from the machine to a terminal board, from which the leads are taken out. The terminal board consists of two heavy slabs of marble, one secured to the machine and the other forming a removable cover. This cover on its inner face is divided into partitions, so that when in place each terminal is in a compartment by itself. It is so arranged that fuses may be inserted in the leads, if desired, as an extra precaution against short circuits. This convenient form of leading the wires out of a dynamo is made possible by the absence of collectors or commutators. By simply changing the connections on the board the armature coils may be connected either in series or parallel, so that the standard machines may be connected for either 1,000 or 2,000 volts, as desired.

The field or exciting coil is circular and wound on a copper spool, which rests in the centre of the machine, surrounding the inductor. It is thus easily insulated to a very high degree, and, being enclosed on three sides by the heavy copper spool, danger of breaking down the insulation due to a discharge caused by breaking the field circuit when it is fully charged is practically removed.

The following efficiencies are given for the several types of machines:—

—	60 kw. Per cent.	120 kw. Per cent.	240 kw. Per cent.
Efficiency at full load	94	95	96
" " half load	91	93	94
" " quarter load	85	88	90

There being no moving wire, it is safe to run this type with a closer clearance than is advisable with other machines, even of toothed armature construction. The design also permits of abundant ventilation, so that it runs unusually cool. The maximum rise in temperature above the surrounding atmosphere is not more than 50°F. in any part of the machine after a continuous run of 24 hours at full load.

One of the most important properties of the machines is their inherent regulation. The designers have proceeded on the theory that compounding in itself is an unquestioned disadvantage, as it complicates the generator, and makes commutation necessary; while it has been necessary, however, in the older types of alternating-current generators not regulating otherwise within 30 or 40 per cent., the new type of generator has an inherent regulation of from 6 per cent. to 9 per cent., depending on the size of the machine and the margin of E.M.F. desired. With one of these machines the full load, excepting one lamp, can be thrown off instantly, it is claimed, without materially increasing the brilliancy of the one remaining lamp (provided, of course, the speed of the machine is constant), and this is accomplished without any extraneous regulating device whatever. It is claimed that there is no possible advantage in compounding when two or more circuits (with 10 per cent. or more loss when fully loaded) are often supplied by a single generator at times when one of them may be fully loaded and the others half or quarter loaded. The vexing problems of distribution are solved by using a closely-regulating machine, and by being more liberal in the use of copper in the line. This liberality will pay for itself many times over by saving in operating expenses, by saving the first cost of all sorts of devices, and by saving in repairs.

As has been pointed out by the inventors of this system, by Kennelly and others, the shape of the current wave generated by a machine is of great importance in order to obtain the best economy in transformers and in the operation of motors by alternating currents. Some of the original types of alternators used in this country, with the surface-wound armature, produced a very good form of wave; but the so-called toothed armature machines distort the wave so that instead of being in the form of a sine curve it is jagged and irregular. In the generator described, the poles, both on the armature and inductor, being stamped out of sheet iron by dies, are all exactly true and perfectly formed, and as the armature is stationary there is no need of overlapping teeth to hold the coils in place, consequently the form of the current wave produced is what it ought to be theoretically, that is, a sine curve. In operating motors commercially this is of great importance, as it permits of the more complete elimination of the false currents. In the ordinary operation of lights it is also important, because with a current of this character the energy lost in the iron of transformers (core loss in watts) is about 10 per cent. less than with the usual form of current supplied by other types of alternators.

If it is desirable to run alternators coupled in multiple it can be accomplished with this generator, from the fact that the poles on any two or more machines, both on armature and inductor, being necessarily exactly alike, the form of current wave must be the same from all the machines and coincide at all times. The close regulation of the machines is also an important factor in this connection.

The alternating current motor that shall fulfil the conditions imposed by commercial service must possess the following characteristics:—It must start from any position of rest with a torque considerably greater than its running torque; it must maintain constant speed under maximum variations of load and its operation

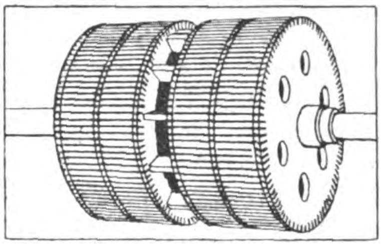

Fig. 3.—Two-Phased Armature (Unwound).

must not unduly disturb the potential of the system. The further qualities of simplicity of construction and operation, and of efficiency in converting electrical energy into motive-power are, of course, necessary.

It is thus evident that synchronous motors cannot fulfil these commercial requirements, for they cannot start from rest with sufficient torque. Alternating current motors of the induction type, either for single or multiphase circuits, have the disadvantages due to the false currents developed by such motors; the difficulty of making them with good starting torque without producing very excessive false currents, and the impossibility, because of these false currents, of producing a comprehensive system for both light and power fed by the same dynamo and circuits. These false currents react on and abnormally demagnetise the generator and transformers, thus introducing difficulties in regulation. They also would make necessary the use of generators, lines and transformers disproportionately large for the work to be done. In a

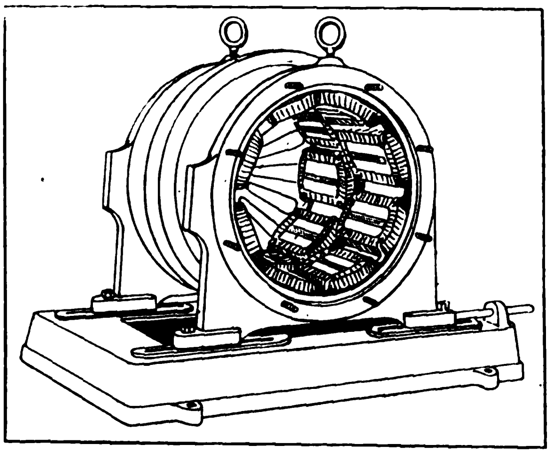

Fig. 4.—Two-Phase Motor Field.

commercial system for distribution of light and power widely throughout the city, motors which take current about in proportion to their load are essential.

Another reason why alternating motors have not been introduced in this country has been because of the high frequency here adopted, at which the false currents are much greater than with lower frequencies, and their disturbing features more difficult to overcome. One object of the Stanley Company has been to produce a motor which would be commercial on the standard frequencies used in this country in order to, in a great many places, simplify the problem of adopting multiphase apparatus because of the vast amount of money already invested in generators and transformers only adapted for this high frequency.

The "S. K. C." motor is novel, and its principle of operation may be best described as consisting of two parts, a motor proper and a rotating transformer, the two parts alternately exchanging

Digitized by Google

their functions. It consists electrically of two fields, which are fed by currents differing 90deg. in phase, and two armatures, though mechanically there is but one. The winding is so connected that the wire which lies directly under poles on one armature is in series with the wire lying between poles on the other. It is clear that in this position one-half the machine acts as transformer and the other half as motor. The motor armature is shown unwound in Fig. 3. The armature winding is not connected with the circuit, and consequently the only current flowing in it is an induced current.

The field construction is shown in Fig. 4. The coils are wound separately, and then secured in place. These coils are the only part of the motor connected with the circuit. Being stationary, they are easily insulated to a high degree. The applied E.M.F. on the coils is 500 volts.

The most unique and striking feature of this motor system is the use of the condenser, the function of which is to make the motor take current in proportion to its load substantially as direct-current motors do. The condensers are connected in multiple with the fields of the motor; and when so placed they supply the lagging component of the current, or, in other words, the false current. Thus, with this arrangement, the false currents, instead of flowing back through the transformer line and generator, thereby disturbing the whole system, simply flow in a local circuit through the condensers. This enables alternating current motors and lights to be operated successfully from the same generator and circuit. Without condensers it is claimed that alternating-current motors cannot be operated on the same circuit with lights on currents of high enough frequencies to meet other commercial conditions. The condenser in use is no trouble and does not complicate the system. When once set up in place there is nothing to do to it, being like a transformer in this respect. Much study has been given for the past two years by the Stanley Company to the manufacture of condensers for commercial use with its motors, with the result that they are now guaranteed thoroughly reliable and inexpensive.

THE LONDON TECHNICAL EDUCATION BOARD.*

ENGINEERING, SHIPBUILDING AND METAL TRADES CONFERENCE.

The second of the series of Trades Conferences, called by the Technical Education Board of the London County Council, was held at the County Hall, Spring-gardens, on Wednesday, 20th inst., at 8 p.m., Mr. Sidney Webb, L.C.C., presiding. The following points were suggested for the consideration of delegates and others taking part in the conference :—

(1.) Training in public elementary and continuation schools.

Whether greater facilities than now exist should be offered to children to continue at school for two years after passing the sixth standard, and the nature of the instruction to be provided.

(2.) Continuation of education after entering the trade.

(*a*) The desirability of having technical schools for members of the engineering and metal trades open in the day time, and the steps, if any, to be taken to make it possible for young apprentices to attend these schools for, say, two half-days in the week.

(*b*) The modifications, if any, required in the organisation and teaching of evening classes in such subjects as geometry, elementary mathematics, applied mechanics, steam, mechanical engineering, pattern making, metal-working tools, machine design, naval architecture, electricity, electrical engineering, and the corresponding laboratory work, &c., and the desirability of teaching the principles of these subjects to members of particular trades, apart from other students, so as more definitely to direct the teaching into useful channels.

(*c*) The best methods of combining sound instruction in principles with practical training in mechanical processes, and generally the best way of associating the theoretical class teaching with the school workshops.

(3.) Special training for those who desire to equip themselves for appointments as foremen or managers—

(*a*) The desirability of providing day teaching of an advanced character in a technical institute provided with an experimental laboratory, and the nature of the aid which would be necessary to enable workmen to take advantage of such teaching.

(*b*) The character of the teaching to be provided, whether in day or evening classes, for foremen or managers, particularly with reference to machine drawing and design, the setting-out of work, principles of the steam engine, the management of machinery, &c., and, for electrical engineers, the methods of electric testing.

(4.) The manner in which the Technical Education Board can best render aid in connection with any of the branches of teaching work indicated.

(5.) The means available for making known to members of the trades, especially to apprentices, the educational facilities provided.

The CHAIRMAN briefly introduced Sir John Hutton, Chairman of the L.C.C., to the delegates.

Sir JOHN HUTTON said he need scarcely say how pleased he was to have an opportunity, through the courtesy of his esteemed friend and colleague, the Chairman of the Technical Education Board, of welcoming them that evening. He regarded it as a most interesting occasion; in the first place, because that was a picked audience, consisting of delegates from various trades and associations, and an audience not only competent to express their views upon the subjects which would be brought before them, but also views that would be of practical value in the administration of the Technical Education Board. In addition to that, they were present for the purpose of helping the younger men who were coming on. No one could say that the object of their presence was their own immediate financial or trade advantage, and he rejoiced to know that that spirit animated them. That he said in no patronising sense, but as a very humble co-worker for the public good. Might that spirit grow and multiply, and still grow on. It was his profound belief that workmen had advantages to their hand of which they had not taken the full benefit up to the present, and that there were opportunities in London which from past neglect had remained absolutely unrealised. It was an old grievance that London was far behind foreign countries in technical education; and when they said that they often with a sigh passed on to consider, not how to remedy that state of things, but how grievous it was, and then the subject dropped. Happily, they lived in better days, and the Technical Education Board of the London County Council had set itself, during the last eighteen months or two years, to seriously consider the question. He ventured to think that the neglect of the subject in the past had been largely due to the fact that it was of very slow growth, and perhaps the spirit of the age was "small profits and quick returns." It reminded him of walking in an avenue of oak trees, realising the pleasant shade of those trees, and forgetting that they were once acorns. Now, that evening they were implanting in the soil of the London technical education schools those acorns which, if properly planted, would germinate and fructify until they produced a giant forest, under the shade of which many a worker yet to come would find refreshment and encouragement. The first conference had been devoted to trades which might be considered as affecting the comfort of home life, but on the present occasion they had to consider trades of greater magnitude and importance, and which in a very distinct sense affected the safety and the welfare of every resident in the country. To engineering they owed those so-called wonders of the world, the pyramids of Egypt, the Roman aqueducts and magnificent roads, in construction scarcely equalled, certainly not surpassed, by modern science. Then they had the civil engineering of the present day, their railways, docks, harbours, bridges; and the desire of the Technical Education Board was that men—the men who were coming on—should have a grasp of the theoretical and the practical parts of the work, without which perfection could never be attained. The Board desired that there should be worthy successors of such men as Smeaton and Brindley and the two Stevensons, father and son, and many others. It was related than an eminent man had been accustomed to raise his hat when going through any of the public schools, because a future Lord Chancellor of England might be in that school; but he (the speaker) did not know but that they could better do without a future Lord Chancellor than without eminence in the engineering art, and, if reverence was due from them to those who in the future might be excelling in a particular walk of life, they might well raise their hats to those boys and girls who were being employed in their technical schools. With regard to shipbuilding, if, unhappily, it was a matter that did not practically interest them in London, they were consoled by the fact that 70 per cent. of the commerce of the world was in English ships, and, although it was true that London in this respect was not the London of thirty or forty years ago, when from Northfleet to the Pool could be seen signs of the shipbuilding industry, still, they were rich enough in wealth, and, he hoped, in talent also, to be able to instruct their young men in this art, so that they might carry their knowledge of it to other centres of industry. With regard to the metal trades, they perhaps offered a special induce-

* From the *Technical World*.

Digitized by Google

ment to educated youths, because they might always feel themselves to be on the verge of a discovery in science which would mean a fortune to themselves and, what was infinitely better, a benefit to mankind. Who 20 or 30 years ago would have thought of steel rails for railways? and science had still secrets not yet divulged in regard to the combination and treatment of metals, which offered a wide and interesting field for the intelligence of the young men who were rising around them. He hoped the spirit of mutual goodwill might prevail and grow and multiply, and the dignity of labour be a reality, and not a sham, to be known and felt of all men.

The CHAIRMAN, after the eloquent words of welcome they had just listened to, would not trouble them with any remarks of his own, beyond two or three connected with the business before them. The Education Board had no views or fads of their own; they were in the position of learners. They desired that whatever work was done in London in the direction of technical education might be turned towards the turning-out of perfect workmen, and not wasted in increasing the number of smatterers. He would ask the delegates to address themselves to the agenda on the paper before them, not dealing with the subjects one after the other, but generally, and, perhaps, they would get on better without moving any formal resolutions.

Mr. STEWARD (London Trades Council and Silversmiths' Association), addressing himself more particularly to the subject of gold and silversmiths' work, said there was a sad lack of education in technical drawing, such as young lads and men would adopt in their particular branch of the trade. In no school were lads taught how to adapt design to work in metals like chasing and *repoussé* work. He hoped the Board would see that the education given included technical and artistic drawing. Then, with regard to confining the education to boys intending to engage in the trade as a livelihood, he instanced the New Cross Institute as one where the education was extended to any and everyone who cared to avail themselves of it; a carpenter it might be, or an engineer, or a joiner, and so on. It would be well if the minds of the delegates could be made clear as to whether the Board intended to give assistance to those schools in London in which everyone was free to come in. Again, some principles would have to be laid down in separating the men engaged in the various branches of a trade in the workshops; for instance, the pattern-maker from the engineer, and the zinc-worker from the tin-worker, &c. In the silversmiths there was a clear distinction made between the silversmith and the spoon-maker; the latter was looked upon as the silversmith proper. If enamelling and engraving were distinct branches of the trade, and if plate-working and goldsmith's work were distinct branches of it, so must chasing and repoussé work be also. He might suggest, also, that if it was decided to teach the lads modelling, it could be done simply and effectively by allowing them to model in clay and wax. That would be a great help to the stonemason, the carver, and even to the architect, as well as to the gold and silversmith. If they set them to work to learn to manipulate metal, they must first teach them a good deal about the technique of the metal, and that, the speaker thought, involved a waste of time. Then there was a great need of good teachers. Men were engaged not so much for their abilities as because they were willing. That might be attributable to the inability to offer decent wages. Thus they might find a metal graver teaching repoussé work and so on, whereas the teachers ought to be specialists. It might not be essential for every teacher in a school to be a practical man, but he did urge, and the whole of his fellow workers urged, that the teachers in the special classes should be specialists in their class. As regards the lads, it was a frequent complaint that they would not be got to attend the classes. If the masters could be induced to allow their apprentices at least one half-day in the week in which to attend the schools, it would be a great gain. He thought the falling-off in attendance might be due to the boys being set to do hard-and-fast things after being at work all day in the workshops. Discipline was a very good thing; but encouragement was desirable also, at any rate in making a start. The whole of the metal trades were agreed that the classes should be held in the centres where the workers reside.

The CHAIRMAN explained, with regard to evening classes, it was laid down in the regulations that instruction was to be given in the subjects mentioned only to those students who were actually engaged in some branch of the trade to which the subject of the class had reference. The rule had not been found so easy in application as might have been expected, and the Board would be glad to receive suggestions on this point.

Mr. ROBINSON (United Pattern-makers' Association) said he knew something about pattern-making, having been engaged in the trade for some 33 years. He understood the object of the Conference to be to elicit such information as would best enable them to educate the young workman in the principles and sciences of his craft, so that he might be a better and more efficient workman and of more commercial value to his employer. Taking an average pattern-maker in a well-appointed engineering firm, in addition to the elementary rules of arithmetic, he should be well up in vulgar fractions and decimals, and he must have a fair acquaintance with plane and practical geometry, not as geometry was taught in the schools, but as applicable to his work. He had known young men, well educated in the sense of having been to school under the ordinary schoolmaster, who, if called upon to apply the most elementary principles of geometry, such as to construct a perpendicular line on a particular base, were utterly at fault. A pattern-maker must also have a good knowledge of mechanical drawing, not that kind of drawing which consisted in being given a subject to copy, which the schoolmaster himself did not understand. Those present who had copied a screw would know what a trying and tedious work it was, and especially to a young man who had been at work all day. But, by explaining at the same time how the setting-out of that screw would have to be applied, they would get greater interest thrown into the work, and the instruction would be of more value to the boy when he went into the workshop. In the small engineering shop technical education was of the utmost value to the pattern-worker, because, if in the large engineering shop draughtsmen were employed to work out details, in the small shop the pattern-worker had to rely on his technical training received in the school. Therefore his knowledge of mathematics must be extended, and he must possess a knowledge of the mechanical details of his craft. He must know, for instance, the relative stress of metals, the contraction and internal strain of iron and light castings, &c. So far as the Board aimed at imparting technical training to *bonâ-fide* apprentices in pattern-making, they would have the sympathy of every workman in the trade. He was not one of those who were frightened by the German bogey. From his 30 years' experience he was quite convinced that the British workman was able to hold his own. The Board should establish its schools in convenient centres, and boys who showed special aptitude should be given opportunity for extending their studies after receiving a general technical training. The boy himself, the master, the workmen, and the trade were all interested in his turning out an efficient workmen. The nation also had an interest in it, and the expense should be borne by the parties who would benefit by it; and if the workmen were to be called upon to bear a portion of the expense, they must also have a voice in deciding how many, and what boys, should be brought into the trade. So far as the technical education was confined to the boys, *bonâ-fide* apprentices in the trade, the Board would have the sympathy of every workman engaged in the trade.

Mr. SENIOR (Electrical Trades) wished to draw attention to a very serious question so far as employés in the electrical trades were concerned. The electrical industry was as yet in its infancy, and, he regretted to say, in a very crushed condition. He welcomed any measure that tended to improve its condition. It was a trade that technical education had much to do with. One of the greatest of the evils he complained of was the tendency among electrical firms to sectionise. That was a system which, if not checked, would end in flooding the labour market with incompetent and unskilled workers. What was necessary was that the boys entering the electrical trades should receive, not only a theoretical but a practical knowledge of electrical science and of the trade generally. They entered quite young into the business, and with the promise of a complete and practical education to fit them to be electrical workers; but such was not the case in practice. They were put upon a certain class of work, kept at it for years, and finally left the workshop with only a partial knowledge of their trade, and ready for any job that was offered, not through any fault of theirs, but of the system. To take an illustration: He had known of youths being put for five or six years to wind bobbins for electrical bells, and other trifling things. The employer was thus able to produce an article, but not by a skilled workman. He hoped the Board would endeavour to devise a way by which boys in the electrical trade would receive a practical training. He would also urge that none but those who intended to get their living in the trade should receive that training. The schools at present were glutted with students in electrical science. Of course, the instruction they received was mainly theoretical, but they would, doubtless, be prepared to take advantage of a practical training if allowed to do so, and the trade would be over-manned.

Mr. JAS. POOLE (Horological Institute) endorsed the remarks of the previous speaker to a great extent. Unfortunately, the system to which Mr. Senior referred was frequently governed by the price which the employer could get for an article, as in the case of a Government contract the price which the Government would give. It was impossible in such a case to make a thing at anything like a profit, unless by sectionising the work to the utmost. A workman would find it impossible to earn a bare existence at the prices paid for the work. The same difficulty ran through all the trades. In the Horological Institute practical classes were started in the year 1880, subsidised by the City and Guilds' Institute to the extent of £350 per annum, the greater part of which was spent upon the teaching staff. Only a very few lads attended the classes, and

Digitized by Google

those who did took their own time over the work, which was simply an amusement for them. The trade, as a manufacturing trade, and as regards its position as a national industry, had not been benefitted at all by any education which those youths had received. He attributed a great deal of the failure to the training being too much open to anyone who liked to make use of it, and who, as a rule, simply did so as a kind of advertisement. Such people went through a course, obtained a certificate, and then set up as retailers on the strength of it, spoiling everything entrusted in their hands, while the real solid work was done by men who were scarcely able to write their own names. When any work was to be done they had to fall back on the old, partially-educated men. A little knowledge was a dangerous thing, and a thing might be a great deal better done by men who did not pretend to much education, but simply did what they were told. He thought they had got beyond the time when employers knew nothing about their business ; still, it was necessary that the workmen should feel that the employers understood the orders they gave, and, therefore, he urged the necessity for education for employers, that they might not be above their business as they often had been.

Mr. Coates (London Association of Foremen Engineers), as one of a representative body of London foremen, thought he could speak with some authority. He had been in charge of workmen in different branches of the engineering trade for over 30 years, during which time he had seen the rise and growth of technical education ; and he would say at once, from his experience, that so-called technical education had spoiled far more fairly good workmen than it had produced. In the first place it was a misnomer. Technical education should be something which taught a man a better way of performing the work by which he was to earn his living. It mattered little to him that a man had learned the differential calculus if he could file a key into a wheel only indifferently well. So far as producing work was concerned, and the filing of the key into its place in the time and at the price at which it could be sold, such training was absolutely useless to the employer. And, as regards colleges, he had had some 16 gentlemen apprentices, who had not received their training in the ordinary School Board technical classes, but in some of the colleges, and with one exception not one of them had ever done a piece of work worth looking at, although they spent six or seven times the time consumed by the ordinary workman. The failing of all the technical instruction he ever came in contact with was that boys were set by the teachers to do things quite irrespective of the time which should be occupied in doing them. Until the commercial element of time was introduced, technical education would be a snare.

Mr. Musin (Tin and Iron Plateworkers) endorsed much that had been said by Mr. Steward ; but in the case of the pattern-makers, his own section of the trade was more fortunate. They had to thank the Polytechnics and the City and Guilds' Institute for having given them practical technical classes in which apprentices were taught by practical workmen, who, after working at the bench all day, took charge of the lads at night. The technical education they required was to teach them how to cut out patterns and to deal with metals for their various purposes. For that not merely theoretical teaching was required. To most of these classes, he believed, workshops were attached. He had been surprised to hear it said that evening that technical education was no good. Some years back, as an apprentice, he looked about him in vain for a class of the description of those that were now flourishing. He had had to go to various geometrical classes, and to wade through an amount of unnecessary work to obtain a little practical knowledge. Now-a-days they had classes which taught the very thing that was required in his particular trade. Several of the lads working in the same workshop as himself were superior to many of the men in producing patterns for the work they had to do. At the same time, they were not altogether complete on the matter. For instance, these classes were not connected with the trade. He thought that every technical class should in some manner be in touch with the union or trade it represented. As to the question whether facilities should be given for apprentices to attend the classes in the daytime, he had been told by teachers that it was difficult to get apprentices to go practically into their trade after a hard day's work ; they tired of it. The only way, therefore, was to endeavour to get the masters to see the necessity of allowing their apprentices some time during the day in which to attend the classes and obtain the technical knowledge which it was almost impossible to get in the workshop, where every man was at his bench, and who, if he had the will, had not the time to teach apprentices their business. He would also urge upon the Board that in all classes the teachers should be men engaged in the trade which they taught. As to making the existence of these classes known, he suggested that those who belonged to trade unions, and workshops connected with unions, should endeavour to persuade the young men to take advantage of these opportunities for technical education. A word from a man urging a young man to go forward would do far more than all the bills and newspaper paragraphs that might be printed. They in the trade he belonged to were thankful for what had been done ; but, for himself, he would wish that the trade should be in touch with the classes, and have some authority in their guidance.

Mr. Barrett (Barge-Builders' Union) said he did not know whether the Board intended to ignore the barge-building trade of the London river. There was no mention of it in the agenda ; but, however that might be, he could assure them that the barge-building trade of the London river was entirely a separate trade by itself, and had been so from time immemorial. Believing that the rising generation and the lads now serving their time would have their interests well looked after by the Technical Committee, he would confine his remarks to the subject of the technical education of workmen in the trade. These should have at least an opportunity of learning the practical basis of their trade. He did not suggest that the members of the trade did not already know the practical part of their business, because he believed the great majority of them did, having had the opportunity of working at it ; but very few of them would, if they were asked, be able to tell the reasons why steel, for instance, should float, or why wood should float, simply because they had never been educated to understand such matters. The Board should, he thought, offer the workmen in the trade who were desirous of it, and he believed many of them were, an opportunity of learning the practical principles of the barge-building trade, and also that they should be allowed every opportunity to attend the various technical institutions in London. He urged this more particularly because he did not doubt that many of those present when they crossed the river, and looked at the craft going up and down, must have felt, as he felt, that the barges were a disgrace to such a country, and not merely to London. That was not the workmen's fault, but the employers', and they would never get the Thames to look handsome (as he believed it was the wish of the London County Council to make all London look handsome) until they improved the appearance of their barges. He did not know whether the Board supplied the implements necessary in technical education, but he wished to impress upon them that the men in the barge-building trade would be only too glad to take advantage of any scheme the Board might have in view.

Mr. Reginald Middleton (London Chamber of Commerce) said he would tell them, in the first place, why he was able to speak to a number of practical men. He had served his time at Stevenson's in Newcastle, had been through the workshops, been a pattern-maker, an engineer at sea, had built several large bridges, was a civil engineer in practice in London, and also an instructor in surveying at the Central Institute of the City and Guilds of London. Drawing was, in almost all cases, the foundation of all technical education. A man who could not draw was generally more or less useless in pattern work. The first step to be taken in almost all cases was to educate a man to draw. The writer who said that to draw a pint pot accurately was in itself a liberal education had only said what was true. As regards the teachers in the schools, as a teacher himself he might be able to say something. When first he went to the Central Institute he took up a perfectly new pupil who had had no experience in the work he had to teach. The subject had been previously dealt with very lightly, and, indeed, was very little known in the college. Since then he had gone on teaching perfectly new students every year for five years, and the effect of teaching in that college single new pupils who had never seen him before was that they knew more than the first pupils knew when they left, simply because they talked amongst themselves about the lectures he had given them. The best teacher was not necessarily the best workman, as the best critic was not always the best author. The art of teaching was one which came to some naturally, to others it came with great labour, and to many it was quite impossible, although they might know the work itself thoroughly. He thought they would find that when the technical schools were commenced the teachers would come of themselves. But they would have to begin with men who, though skilled workmen, were not very good teachers, but who would, in many cases, develop into good teachers, and where they did not their places would be taken by their own pupils in time, who would be good teachers. Exactly as drawing was a great desideratum, so was modelling. There was no reason why a man who had learned geometry in the schools should not know geometry in the shops. If he did not do so, that was merely because he had not been properly taught. A speaker had said that from his experience technical education was useless. Speaking of the college, with which he (Mr. Middleton) was connected, he thought that if the author of that remark only knew the students there, he would admit that technical education was most valuable. When he served his time in Newcastle there were absolutely no means of obtaining technical information ; he had had to pick up what he knew in the shops from the men, who, of course, were not educated in any technical sense, but simply knew the best way, as they thought, of handling their tools. He had had to learn the practical part of his business first and the theoretical part afterwards with much pain and labour in the course of his daily work. Now all that was changed, and the young man

Digitized by Google

who had just gone through college came out of college knowing more than most of them, like the speaker, knew after ten years' work. A proof that that was so was that many of those pupils had, only two or three years after leaving college, obtained managerships of various works in London, entirely through merit, and without being pushed at all, and were found to be more valuable to the employer than the man who had served the same time in the office. In the course of his own professional work he had had a good many pupils, but those he had had from the Central Institute, who had come to him with very little practical knowledge, had picked up that knowledge far more readily than the others, and had become far more useful in much less time. Under these circumstances he thought they might say that technical education was valuable. He agreed with the same speaker when he said that technical education was to teach the pupil the work of his life. If what he was learning was not the work of his life, it had better be let alone. Technical education should be that, and therefore the teaching should be directed as much as possible to the work in which the pupil was to be engaged. But, at the same time, any information he might pick up along with it would be so much gain. With regard to sectional work, he was aware that it was a great grievance to many; but he was afraid that the tendency of the day was entirely in support of it. In the speaker's own profession, the man who took up a specialty was the successful one. Another individual might be more useful in more branches of his profession, but he was not the man who got on. In America, where mechanics were paid much more highly than here, the tendency to sectionalise was far greater, and the work turned out was generally better done and cheaper for that very reason. After all, everything depended upon the commercial value of the thing. If they could not turn out a good thing and very cheap they would not get the work, and in order to get the work done well and cheaply it was necessary to sectionalise. Watchmaking, sewing-machine making was better done when sectionalised. Another speaker had said that he was not afraid of Germany. It did not do to undervalue one's opponents. He had travelled a great deal, both on the Continent and in America, and he had seen that the people, who in his youthful days were far behind the English in mechanical knowledge, were, in many cases, now far in advance. There were branches of engineering which were far better understood on the Continent than in this country; for instance, in Switzerland, where they had much water-power; and he was afraid they must give the palm in all stationary engines to Germany. The Germans made better engines and understood them better than we did. He strongly advised the Technical Education Board to advance, not too fast, but as steadily as possible, and he advised every workman to be prepared to take up sectional work when it came.

Mr. Harrington (Zinc Workers' Society) said the zinc workers seemed to occupy a place all to themselves. It had been left to them to inaugurate their own classes. Four years ago, seeing the efforts made by other trades for their young fellows, they had thought it their business to do the same. They had a difficulty, seeing they were not subsidised, until the Regent-street Polytechnic came to their aid by placing their rooms and appliances at their service, and then they started a class and had had a remarkably good attendance, and some of the most able men in the trade as instructors. They had had a first term, a second, and a third term, at the end of which their funds fell very low, and they had no subsidies. It then occurred to them that, as other classes had their teachers paid for them, the zinc workers might also enjoy that advantage. They wrote to the governing body of the Regent-street Polytechnic, asking that they would subsidise their teachers, and that they might have three teachers at the minimum of five guineas a term. The governing body referred them to the Technical Instruction Board of the London County Council, who, after considering the matter, said they already paid a very large sum to the Regent-street Polytechnic, and referred the society to them. The Board were not aware that any class in the Polytechnic was in the same position as the society, and they left it to the Polytechnic to say what they would allow. The society wrote to the Polytechnic some two or three months ago, but had not had a reply, not, he was sure, from any want of sympathy with the society. Having thus fallen between the two stools, the society looked with confidence to the County Council. As to practical education as well as theoretical education, he thought it most valuable. The two should go hand in hand. In their own class they had some young fellows exceptionally sharp, and others not so sharp, able to follow instructions in a methodical sort of manner, but afterwards completely in a fog. If they had only practical education in applying the theoretical training it would be of the utmost advantage to them. Happening to be one of the Lord Mayor's delegates to the Paris Exhibition, he went one evening to the headquarters of a trade society very closely resembling his own, to which (although not subsidised in any way, so far as he could understand by means of an interpreter) a man who wanted to know anything might come and ask his more instructed fellow-workmen how to set about it. One portion of the building was filled with large models, and workmen were there demonstrating the practical part of their work to their fellow-workmen freely.

Mr. Eldridge (President of the Silver Trades Council) ventured to say that the gentleman who spoke of technical education as useless had spoken in sheer ignorance. For himself, he served his time as an apprentice in the silver trade for seven years; but, as regards the constituent parts of sterling silver, he had had to learn them since. Such ability as he possessed he had had to learn in other ways than in the shop. As President of the Silver Trades Council, representing about 1,000 organised workmen in that trade, he was anxious to emphasise and to urge upon the Board the importance of only giving instruction to those already engaged in the trade, or who were going to get their living by it, and of only supporting those schools that did give instruction to men working in the trade. They had no wish to confine the teaching to the particular branch in which a young fellow happened to be engaged; they would as far as possible have everybody engaged in a trade to know the general principles of that trade, as otherwise he would become a drug in the market, and tend to reduce wages instead of keeping them up. Had there been technical classes when he was an apprentice he would gladly have availed himself of them. In that case he would not have been obliged to accept such a small wage as he had done after serving seven laborious years at a wage which, had his parents not been in a position to maintain him, would have been quite insufficient for his needs. Though ability would always tell, however uneducated a man might be, still technical education would assist him far more than he could hope for without it, and a man who had the ability to be head and shoulders above his fellows, with better education, would be entitled to rise still higher; it would be also to the advantage of those with whom he worked and to the good of the trade generally. The only fear they had was that in a trade which dealt in luxuries the purchaser might not be himself sufficiently educated to be able to understand a thing when it was made, and to estimate it at its true commercial value. The difficulty was to produce a common article to suit the taste of the purchaser. The need was that the purchaser should be educated above the workman, so that he might know a piece of good work, and why it was good work. Technical education was bound to tell among the workmen; they would be better workman because more intelligent. It was also absolutely necessary that men engaged in ornamental work like his own should understand both modelling and drawing. It would often be of the greatest assistance to a workman to be able to set down on paper his ideas, instead of having at first to make the article before they could find out where their mistakes lay. The Board could not do better than continue to give this education, and, speaking for his own trade, and the branches associated with it, they would do their best to assist in laying the needs of technical education before the young men and boys who came into their trade. He wished every success to the efforts of the Board, if only they would adhere to confining it to the men engaged in the trade.

Mr. Sellicks (Chairman of the Council of the Amalgamated Society of Engineers) said the general sense of the meeting seemed to be that only those who intend to follow a trade as a living should be taught in the technical schools. After the Chairman's announcement that the Board had adopted that principle, it was unnecessary for him to make a point of it. One thing, however, seemed to have escaped the attention of the delegates, and that was the extra strain upon the physique of the boys when called upon to attend technical schools after a day's work. He would like to move a resolution dealing with that, because if the discussion should go on without focussing the ideas of the delegates at all, except for expressions of opinions, they would not reach any definite end. He would read the resolution he intended to put as follows:—

"That in the opinion of this conference, the advantages arising from technical education being of national importance, it is desirable that some provision be made by employers to enable apprentices to attend school in the daytime, and in the event of the Technical Education Board not being able to effect this by any other means, powers should be sought from Parliament to enforce it."

Continuing, Mr. Sellicks said they had already a compulsory Act of Parliament making what are called "half-timers," and it was as reasonable to expect that Parliament should enforce the allowing to lads of time in which properly to acquire the theoretical and practical part of their trade. He had practical experience of the inroads which these overtime studies could make upon the health of a boy not over strong. The resolution, he ventured to say, was one which most of them would sympathise with. Even should the employers be compelled to pay the lads it would not be a great expense to them, besides being to their advantage that the lads should be properly taught; and, if the employers could not afford the expense let the nation pay the cost, for if it were to the employers' advantage it was equally

Digitized by Google

so to the nation. In regard to competition, it was regrettable that things had to be turned out at a certain price. They often heard it charged against workmen that they scamped work. He took it that the majority of those present were workmen, and would be prepared to endorse that charge. He maintained that the British workman of the day, given the chance, was as capable of turning out as fine work as was done in the Middle Ages, in any branch of the trade; but they could not do it if they had to compete and struggle. The cart was always at the door, and hence this hurry-scurry over the work and this eternal competition, and the employers turning round and charging the workmen with scamping their work. The employers imagined that they scamped it from choice; but nothing of the kind, a good mechanic loved his work. That should be the object of technical education. He believed it to be of immense value.

Mr. IMERSON seconded the resolution, which was carried *nem. con.*

Mr. PURVER (Wheelwrights' Society) said the technical education scheme seemed to him a good one; but, as a wheelwright smith, the question to his mind was how would it affect his particular industry? The apprentice system, as far as his trade was concerned, was long since dead and buried, he hoped never to rise again. Under that system the employers, having received a small premium with the boy, the apprentice was left to learn as little as he might, and then passed out to join the great army of the unemployed and unskilled workmen. If the Board wished to do the wheelwright trade any practical good Mr. Webb must use his influence upon the Council to obtain for the workmen better conditions under which they might work. That might do a great deal of good. At present what was desired was rather quantity than quality. They had not the time to consider a nice piece of work. A workman who might look twice at one job would be discharged. The masters needed educating as much as the men—in fact, they needed it more. If the masters would only realise that the better the class of work turned out the better for them in the long run, they would give the workman a chance to turn out a piece of work he could take some pride in.

Mr. WELLS (Wheelwright) also feared that the apprentice system was dead in the trade he belonged to. Boys in the wheelwright trade were left to pick up what they could. He would view with great pleasure any scheme for educating youths in the trade, as at present they practically received no training at all. The Wheelwrights' Society would certainly give their support to technical education.

Mr. JAS. RIGG (Rigg's Engineering Model Company) would point out the importance of drawing to mechanical engineers. He himself attached enormous importance to it, and in the case of his own apprentices, had insisted on their attending drawing classes in days before this technical education was thought so much of. Many of them now held important positions entirely owing to his having insisted on their learning drawing. He thought the Board might well use its influence with mechanical engineers to induce them to modify in some respects the system of apprenticeship. If manufacturing engineers could be induced to allow their apprentices to spend one-half of their time in the drawing office it would be an enormous advantage to both parties. He believed the technical schools gave a good education, but they were not yet capable of imparting a practical engineering training, which was only to be obtained in first-class engineering works. He would suggest that in the opinion of the meeting the engineering instruction for foremen and managers would be greatly promoted if the Technical Education Board could arrange that manufacturing engineers (during the first two years at least) should spend one half of their time in the drawing office.

The CHAIRMAN suggested that the object proposed by the last speaker would be better attained by leaving it in the hands of the Board. The Board could not very well ask all the engineers in London to allow all their apprentices to undergo that training; but they would do their best to lay it before those concerned to see if anything came of it.

Mr. WALKER (Electrical Trades Union) said he represented the electric lighting installation branch of the trade, and also telephone and telegraph work. He welcomed the work of the Council on behalf of technical education; but the classes should be restricted to men actually engaged in the trade. He found it stated that electric lighting and house fitting were among the trades as to which the Council made it a condition of any grant that this restriction should be observed; but in practice it was not always so. For instance, at the Battersea Polytechnic and the Shoreditch Polytechnic it was not the case. At the Battersea Polytechnic there were less than forty or fifty students in the class, and these included gas-fitters, waiters, potmen, and workers in all manners of trades were being taught in that class to the exclusion of the genuine workman, and, he was sorry to add, given every encouragement. At the present time there were about 3,000 men engaged in the line he represented, and at least 800 of these were estimated to be out of work at a time when the schools were manufacturing electrical installation workmen as fast as they could. In one class gasmen and lamplighters had been offered, as an inducement to learning the trade, that they would be able to earn at it from £4 to £5 a week. He asked the Board to enforce its rule to make no grants unless in favour of those who were solely engaged in the trade. Recently a firm of electrical engineers, having advertised for first-class workmen for electric lighting installation, had received something like 150 answers, and, out of these, nine gave as reference the Technical Schools of Shoreditch and Battersea Polytechnics, and each of them had originally been in some other class of business, labourers principally. The armature and magnet winders were a trade in themselves, and there was great room for improvement there. He hoped the Board would make it a rule, before making grants to any class, to see that armature winding and magnet winding were included in the subjects taught.

Principal H. WELLS (Battersea Polytechnic) did not desire to state that the last speaker was entirely wrong in saying that the Polytechnic he represented did admit men to their class who were not actually engaged in the particular work referred to, but he did say that the last speaker had given an exaggerated view, which was unfair to the position which the Battersea Polytechnic had taken up. Every one of the workshops, with the one exception referred to, was absolutely restricted to trade students; and the reason the restriction was not applied to this one was that at first they very much doubted whether a class could be got at all. When, however, they found the members becoming numerous, he (the speaker) took steps to ensure that the places in the class should be given, in the first place, to the people actually working in the trade. The Polytechnic's position was one of decided sympathy with the general lines that had been laid down.

The CHAIRMAN said that the Board felt themselves indebted to any trade union who might let them know of such things. Although there had been a certain amount of grumbling, the Board had not, he regretted to say, received a single letter from any trade union containing any criticism.

Mr. F. W. GALTON (Silver Trades Council) said much of what he had intended to say was covered by the resolution that had been carried. But, in addition to giving the boys facilities to attend the classes, another thing might be done, especially in the trades he represented, and also in, he might say, all the art trades in London, towards assisting the lads to go and see the wonderful collection in South Kensington. At the present moment South Kensington possessed what was probably the very finest collection of work done by the art trades carried on in London that had been got together anywhere. Then legislators had placed that wonderful collection, not where it might be of use to the workman—that was to say in the east end of London—but in the west end. It might have been placed there to meet the wishes of those who thought that rich people require to have their taste educated up to the standpoint of the workman; but certainly it had the effect of keeping away from the workmen the knowledge, which they could otherwise gain, of the means employed in the trade. In the first place they had not the time, and in the next place not always the money to pay the railway fares. The Technical Education Board had very wisely granted scholarships of £20 to enable young men to attend art classes, and he thought that rule might be broadened a little so as to include anyone who attended South Kensington and showed appreciable work as the result—that was to say, brought back a careful study or drawing of a piece of antique metal or carving—and that it might be held to be equivalent to attending a class. With regard to point (5), when he (the speaker) was an apprentice, not so many years ago, he used to find that when he went to an evening school he was thoroughly tired out, and generally he went to the one which was farthest away, not knowing that there were others in the neighbourhood. The trades unions represented that evening might make a special point of that, and some of the trades might draw up a list of names and addresses of apprentices, which, forwarded to the Technical Education Board, might enable them to bring to the notice of the lads the kind of work that was being done. At any rate, the trades might supply the Board with lists of trade-union workshops, and the number of apprentices employed in them, so that notice might be sent to the workshops, if not to individuals. In regard to the question of teaching to persons not actually employed in the trade, he would not be doing his duty to the resolution passed by the Silver Trades Council, whom he was appointed to represent, unless he laid special stress upon this point. He regretted that the Board should have come to the conclusion that wood-carving and repoussé work were parts of the general art training, as he distinctly thought that repoussé work was part of the trade. To go to the trouble of teaching a boy to manipulate difficult tools and materials, when he could get all the experience he needed by means of clay or wax modelling, was absurd, unless he was going to use such materials in working in the trade, in which case no objection could be taken to it. With the view of restricting the classes to persons within the trades, the Board might make it a rule to restrict the class to per-

Digitized by Google

sons in the trade wherever the trade was one which was clearly defined. For instance, he did not think that the distinction between the fitter and the turner in the engineering trade ought to be maintained, nor the distinction between the heraldic and artistic engraver. But, wherever it had become the rule to regard two trades as distinct, as regards apprenticeship or otherwise, the restriction ought to be enforced. The object of the Board ought not to be teach a large number, but to make those in the trade better workmen. He therefore urged upon them to confine their teaching to boys in the trade at which they were actually at work, or in the one or two branches which did not actually overlap.

Mr. C. E. GROVE (Thames Ironworks Company) said it so happened that the Company he represented had considered nearly all the points raised by the speakers, so long ago as 1887, when they decided to establish their own schools for the instruction of their apprentices, draughtsmen, workmen, and others who might care to come, and also of a limited number of outsiders personally known and introduced by someone in some position in the firm. That had raised the whole question of technical education. There were two broad classes to be considered, first, the draughtsman and the premium-paying pupils. In regard to them, it was the invariable rule that they should spend the first year in the drawing office, in the first place tracing, and then drawing designs on their own account, after which they went into the shops to carry them out. With regard to the other class of apprentices—viz., those who went into the shops and stopped in them, and who were taken into the shops without any premium being paid—they learned their work from the workmen, and steps were taken that they should have as much variety of work as possible. What had been found necessary was that people should have a better knowledge of the scientific principles which underlay the trade, and that the company had endeavoured to secure in their schools. The students who attended these schools, young men from 16 to 20 years of age, and men even so old as 40, were generally deficient in elementary mathematics, and in teaching mechanics he was often brought up by the pupils not understanding the elementary principles. For the sake of those who wanted it, he undertook to give an extra lesson in arithmetic and elementary algebra; and in that class he had 32 students, 30 of whom came to learn vulgar fractions and simple equations. That was where technical education, if it was to be made scientific, must commence; and the Technical Education Board might do useful work if they could raise the standard, so that a boy when he went into the shop might have a little more mathematical knowledge to start with. The company had considered the question of day-class teaching, and had decided to relinquish it for the present, having regard to the inconvenience caused by workmen in different parts of the work leaving their tools standing idle. This inconvenience was the more felt when men in the position of superintendents left their work in the daytime; but, realising that the evening classes involved some sacrifice to the pupils, they had a practice, where a lad showed promise, of giving him a little more money and of putting a little better work before him.

Mr. LOWEN (London Society of Goldsmiths) impressed upon the Board the necessity of legislation to compel the masters to allow their apprentices to take advantage of the opportunities offered.

The CHAIRMAN said the Board were only too glad at any time to receive any suggestions from the trade unions.

Mr. KNOWLES (Battersea Branch of Amalgamated Engineers) suggested with regard to the paragraph 4, that the technical schools should be thrown open to advanced men—*i.e.*, foremen and men occupying positions in shops where apprentices were at work, so that they could have an opportunity of being with the apprentices in the evening.

The CHAIRMAN, in conclusion, thanked the delegates for their attendance, and observed that point No. 5 had been very little touched upon. The Technical Education Board was offering every year five scholarships for children between 11 and 13 years of age to enable them to prolong their training for a couple of years; also 30 to 50 intermediate scholarships to people of the ages of 15, 16, 17, or 18, and a few scholarships to carry the best of these to a first-rate scientific training. The Board also offered a considerable number of art scholarships every year, specially restricted to artisans under 25 years of age, partly for evening work and partly for day work. The difficulty had been to make known these advantages to the classes affected. They were offering considerable opportunities to evening classes in art schools, polytechnics, intermediate schools, and technical schools in London; they had established a domestic economy class for women, and were offering classes, all over London. They asked the delegates to take back to their unions some notions regarding the work the Board was doing, and to see whether they could not help the work, not only by their criticisms and suggestions, but also by helping to make it known. Every word that had been spoken that evening would be carefully considered by the Board.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June* 16, 1894.

The Buda-Pesth Conduit System in New York.—The Metropolitan Traction Company has announced that it has accepted an offer from the General Electric Company to lay down three miles of electric conduit street railway similar to that at Buda-Pesth. The Traction Company will provide the road bed, steam-power and conduit, the latter to be the same as used for cables. The General Electric Company will furnish all the electrical equipment. The road will be tried for a year, at the end of which time, if successful, the General Electric Company will be paid; if unsuccessful, the latter will remove at its own expense all electrical apparatus and material, and a traction cable will be installed. It was unofficially stated some time ago that arrangements had been about concluded with the Siemens-Halske Company for the above conduit road, but it seems that it finally refused, while the General Electric Company accepted a proviso in the contract guaranteeing immunity from damages for infringement of patents.

The General Electric and Fort Wayne Companies.—The strained relations between the General Electric Company and the Fort Wayne Electric Company have at last culminated in an open rupture, and a fierce legal battle has been commenced. The latter Company obtained from a home judge the appointment of a receiver, who at once leased the manufacturing plant to the Fort Wayne Electric Corporation, which is practically identical with the other Company in its personnel, excepting that the General Electric interest is entirely left out. The new concern has already announced a complete new line of electrical apparatus, the design of which had been under preparation for some time in view of the expected separation of the warring interests. A new type of Wood arc machine is included with a capacity of 150 450-watt lamps.

The Pollard Lamp.—An injunction has been granted against the Pollard lamp, made in Boston, for infringement of the Edison lamp patent. In this lamp the usual leading-in wires are displaced by a film of silver deposited on the interior wall of a tube, the connecting wires only entering slightly at one end.

LEGAL INTELLIGENCE.

Re Woodhouse and Rawson United (Limited).

The public examination of the Directors and others concerned in the promotion and conduct of this Company was resumed before Mr. Registrar Hood on Wednesday. The Counsel engaged in the case were enumerated last week, but it should be added that Mr. Butcher, M.P., and Mr. H. G. Rawson represented certain of the parties.

Mr. H. G. RAWSON stated that the books and documents for which the Official Receiver had inquired had been found in the same place as they had been in for months and years past, and where they had been quite accessible to the Official Receiver, whose duties were of a sufficiently inquisitorial character to justify him in making a thorough search. Counsel further complained, on behalf of Mr. Rawson and the other Directors, of such insinuations being made by the Official Receiver as that the documents had been "spirited away." All the Directors courted the fullest inquiry, and were anxious to render every assistance in their power, and it was unfair that such suggestions should be made.

The learned REGISTRAR said that so far as he had been able to observe, subject to any specific cause of complaint there might be, the Official Receiver had conducted the inquiry in a fair spirit and with every consideration for the Directors.

Mr. F. W. PIXLEY, the auditor, once more went into the box, and was asked by Mr. McKay as to the reason for the difference of phraseology in his certificate of the accounts of the Woodhouse and Rawson (Limited) for 1888, and that of the accounts of Woodhouse and Rawson United for 1892. In the first case the statement was that the accounts were correct, "in accordance with" a special report made to the Directors; whilst in the more recent case the certificate more definitely stated that the certificate of the accounts must be taken in conjunction with a special report. Witness explained that in 1888 he simply declined to endorse the value of the profits assumed by the Directors, as to which he had no means of judging; but at the same time he had no reason to doubt the accuracy of their assumption. In the case of the 1892 accounts, he declined to certify to the accounts at all.

A tedious examination followed by Mr. PILLING, whose main point seemed to be as to whether in the last balance-sheet of Woodhouse and Rawson (Limited), in addition to £97,899 shown as undistributed profits, there should have been included the sums of £64,000 for patent rights

Digitized by Google

and £75,000 for goodwill obtained on the sale of the concern to the United Company, so that the real amount of profits to be divided should have been £236,849. Witness admitted that those sums did represent profit, but was unaware whether they were ever realised. After further questions as to whether it was right that the Managing Director (Mr. F. L. Rawson) should have been credited at a particular juncture with commission on sums paid by the Okonite Company, Witness, replying to the Directors, thought the sum should be passed to Mr. Rawson's credit, and Counsel's opinion was taken.

Mr. JENKINS objected to the line of Mr. Pilling's examination, which, he contended, did not come within the section under which these examinations were held. It seemed that this was a hostile auditor trying to get expert evidence out of a brother auditor.

The learned REGISTRAR said it was very difficult to say what did and what did not come within the section, but he must request Mr. Pilling to conduct his examination with a little more discretion.

Mr. PILLING said he was a large shareholder, and had lost a lot of money in the concern, and he contended that he would never have lost a penny of it if the balance-sheet had been properly prepared.

Mr. PIXLEY, at the conclusion of his examination, made the following statement: With reference to the original prospectus of Woodhouse and Rawson United (Limited) issued in July, 1889, it was not, he believed, even pretended that anyone incurred any legal or moral responsibility by simply allowing his name to be placed on a prospectus as auditor. He should, of course, satisfy himself as to the respectability of the Directors, and as to the purposes for which the Company was promoted; but the publication of his name was merely an indication to intending subscribers that he would be the person who eventually audited the accounts at the expiration of the first financial year. When an industrial business was converted into a public company it was usual to obtain a certification of profits from a chartered accountant, who made a special investigation for such purpose; and in this case he was asked to give such a certificate. It was fully in evidence that this he declined, and although a reference was made to the profits shown by the audited accounts of Woodhouse and Rawson (Limited), none whatever was being made to his being the auditor, and no intending applicant for shares had, he contended, any right to assume that such was the case. If he took the trouble to call for the accounts he would then have ascertained that they were accompanied by a special report from the auditors. His sole clients were the shareholders of Woodhouse and Rawson (Limited). At the same time, although he declined to accept any responsibility in regard to those who might subscribe to Woodhouse and Rawson United (Limited), he had no reason whatever to doubt that the profit referred to on the prospectus was absolutely correct, and would be ultimately realised. As regards the issue of the subsequent prospectuses, inviting subscriptions for debentures and shares at a premium, he was never consulted upon them, and they were never even seen by him until after their issue. As regards the balance-sheet, three were issued to shareholders; viz., June 30, 1890, July 31, 1891, and July 31, 1892. During the interval that took place between the first and subsequent part of his examination he had been enabled to look more closely into his notes, which were exceedingly voluminous, and he had refreshed his memory upon several points. As regards the balance-sheet of June 30, 1890, every item on the credit side was investigated by him, and the value set opposite them most carefully criticised. The accounts when first presented to him varied from those ultimately certified. For example, nothing was written off patents until he pointed out that this should be done, the result being that £7,421. 16s. 9d. was charged against the profit and loss account. A great deal of evidence was produced to him as to the values put by the Directors upon the assets. There was included among the debtors a large sum from the International Okonite Company. That Company was successfully floated; and having regard to the fact that the public were subscribing for shares at par, and that a Director of Woodhouse and Rawson United (Limited) was a member of the Board, and therefore more likely than himself to know the value of the shares, he considered that he should have done wrong to have thrown doubts upon the value put upon them in the balance-sheet; namely, the par value. There was, moreover, a reserve or surplus, after the payment of the interim and proposed dividends, of £49,857. 12s., and in the face of that reserve, and from the facts known to him at the time, and after interviews and correspondence with the solicitors of the Company, and the opinions of eminent counsel on some of the important points, he was satisfied that it was his duty to pass those accounts, and he should do so again under similar circumstances. Coming to the balance-sheet of July 31, 1891, he thought there was a misapprehension that after sending the proposed certificate to the Managing Director, the accounts he subsequently signed without affixing the certificate were the same as those before him when he drafted that certificate. That was not so, for many alterations were made in the accounts as the result of the threatened certificate. In the first place it was distinctly stated on the accounts ultimately signed that the debtors were those of May 31st, and that the cash was that of May 31st, a statement being affixed showing the difference between the receipts and payments between June 1st and July 31st. Again, he called attention in the draft certificate to the fact that nothing was written off patents or patent rights and charged against profit and loss. The accounts ultimately signed included the sum of £4,156. 19s. 9d. written off for depreciation of patents. He received also an undertaking by the Directors of the Company that the amount due from Mr. Rawson should be paid off, and also an undertaking from Mr. Rawson himself. It was also pointed out to him that the vendor Company being indebted to Mr. Rawson personally, this Company had full security, and as a matter of fact it was ultimately proved that this balance was extinguished. As regards his calling attention to the fact that the profits on the financial and the industrial business were not separated, he considered it was beyond the scope of his authority to insist on this, and one of the pledges he received was that reference should be made to the financial business in the Directors' report, and this pledge was fulfilled. The audit certificate also contained a distinct statement that the amounts taken credit for—for plant, stock, works in progress, and investments not quoted—had been certified by the Company's officials. At the same time the items were most closely questioned by him, especially the investments, amounting to £119,338. 15s. Of this sum £43,000 consisted of debentures, Preference and Ordinary shares, in the International Okonite Company. In addition to the fact that he knew one of the Directors was on the Board of the other Company as stated, the Stock Exchange Official List of that date was produced to him in support of the Directors' valuation. As regards the Phœnix Trust Company's shares, Mr. Rawson was a Director of that Company, and he informed him that they had in hand about £5,000 already towards the distribution of the next dividend on those shares, and Woodhouse and Rawson United had already received a dividend of £6,900 on them: whilst they expected another £5,000 in dividend shortly. As regards the other shares, the only evidence that he could obtain was that their value was par, and it was a significant fact that in his cross-examination no document had been produced to contradict this valuation. It must also be remembered that, with the exception of the Phœnix Trust, the companies whose shares were referred to were not launched to promote schemes brought to Woodhouse and Rawson United as promoters; they were the results of scientific work, and experiments made by the Company's own engineers in their own workshops. Large sums of money were expended in experimenting and developing those processes, which were tested, patented, and ultimately disposed of to companies in exchange for cash and fully-paid shares. These shares were not, of course, quickly realisable, but the accounts would have been absolutely incorrect had they not taken to credit the value of those shares at their nominal amounts. The expenses connected with the experiments in developing and testing those processes, and the costs of the formation of those companies, were fully charged against the profit and loss account. To provide against over-valuation of the shares there was still, after payment of the dividends, a reserve of £44,000 on the balance-sheet of July 31, 1891. As regards the balance-sheet of July 31, 1892, in the first place he found the books in the greatest confusion, a very large number of vouchers for payments being missing. He also ascertained that the anticipations of the Directors as to the sale of the shares, were not being realised, and that money was being borrowed at high rates of interest. He therefore came to the conclusion that he could not sign those accounts, and affixed a special report to the shareholders calling their attention to the general unsatisfactory position of the affairs of the Company. It had been suggested to him in the course of the examination that it would have been better had he issued such a report with the accounts to July 31, 1891. He admitted that in the light of present knowledge it might have been better had he done so; but an auditor must not act upon impulse, and he considered he was right in signing the accounts for 1890 and 1891. The Board of the Company was composed of men of high reputation, and he had every reason to believe they were acting solely in the interests of the shareholders. Should an auditor suspect that the Directors of a company were misapplying its funds or carrying on the business to their own interest at the expense of the shareholders, he might consider—and he was glad to say the members of the Institute of Chartered Accountants did so consider—that an auditor should step outside what might be considered his bare duty, and interfere; but in this case he had no such suspicion.

Sir JOHN STOKES (examined by the Official Receiver), said he was interested as a shareholder in Woodhouse and Rawson (Limited). He had no doubt that the Directors of the United Company took care to see that they obtained everything in the shape of patents which it was within the power of Woodhouse and Rawson (Limited) to sell, with the exception of certain things specifically reserved in the agreement. Personally he took no part in the negotiations until after allotment, as he was one of the liquidators of Woodhouse and Rawson (Limited). He took no part in examining into the position of the other companies which were acquired; he left it entirely to the provisional Directors, Sir John Coode, Sir Albert Cappel, and Col. Howard Vincent. When those gentlemen retired he did not feel it incumbent upon him to make special inquiry into the condition of those businesses, as their retirement had no reference to them. He was not aware of the fact that the manufacturing company began the year 1889 with a loss of £34,936, which mounted to £44,718 by the end of the year. He learnt, as liquidator of Woodhouse and Rawson (Limited), that the manufacturing Company could not pay their indebtedness in full to the former, but could not say whether they could only pay 10s. in the pound. He knew that amongst the assets of Woodhouse and Rawson (Limited) was an option in the Elmore Company's shares. There was a dispute at the time of the amalgamation as to whom that option belonged, and the Limited Company considered that it belonged to them; he, personally, did not understand that it passed to the United Company. He did not think any part of the inducement to give way in regard to the ownership of that option was that the guarantee fund should be returned; but he had no clear recollection of what the inducement really was. He was, of course, anxious as the liquidator of Woodhouse and Rawson (Limited) to get the guarantee fund of £75,000 back. It might be the fact, but he could not say, that every one of the Directors of the United Company, except Sir Rawson Rawson, was a shareholder in the Woodhouse and Rawson Company. He held the view that generally the interests of the shareholders in the one company were identical with those in the other, and anything he could do to facilitate the liquidation of Woodhouse and Rawson (Limited) he considered would benefit the shareholders of the United Company. The return of the £75,000 chiefly affected the holders of the founders' shares. He did not consider that his position as liquidator of Woodhouse and Rawson (Limited) clashed with his position as Director of the United Company. He understood that the United Company was to conduct both an industrial and a financial business, and there was a clause in

Digitized by Google

the prospectus which referred to that. The prospectus did not suggest that only industrial businesses were to be acquired. He did not think it was right to say that the industrial businesses had shown any profit, for the Limited Company had carried out a good deal of industrial business; he was not, however, prepared to say that it was from that source that the profits were obtained, the transactions in regard to the Elmore Company being chiefly responsible for that. He could not say that the shares in the Manufacturing Company were ever worth anything or not. He could not remember whether the Limited Company ever conducted any successful venture excepting that in regard to the Elmore shares. He considered the United Company, in addition to the flotation of the Kensington Co-operative Stores and the successful use of the option in Elmore shares, made a profit at the time on the Okonite Company. They spent £12,000 in developing the Epstein patents, but whether the shares they held in the Epstein Company were worth that amount now he could not say. He did not know that the Receiver of that Company had offered the 8,000 shares in that Company at 1s. each.

Mr. H. G. RAWSON said there were very special circumstances in that case, and the 1s. only represented part of the consideration.

Examination continued: He thought the money that had been lost had gone in developing the industrial operations of the Company. He could not say it was not a fact that £46,000 went in shares of the Okonite Company. He was ill at the time of that operation. Nor was he aware that £10,000 had been realised by the sale of some of the shares. He did not know the exact date of the formation of the Epstein Company, which the Official Receiver said was July 31st, the last day of the financial year. The value of their interest in the Epstein patent was put down at £35,000; £4,000 had been paid Mr. Epstein for part interest in the patent, and £12,000 was expended in developing it. They had been following up the development of that patent for three years or more, and it was upon their belief in the value of the patent that they estimated the £35,000. There was nothing, except their desire to act as reasonable men, to prevent their putting the profit at £50,000 or £100,000, as no one else was interested except Mr. Epstein and the United Company. He was not aware that on July 31, 1891, only 300 shares were taken apart from those held by the United Company and Mr. Epstein. The amount owing to the United Company by Mr. Rawson was discharged by the former taking over the Debenture stock in the United Company which Mr. Rawson had acquired through the Limited Company. Those debentures were issued to Mr. Rawson at 50 per cent. discount, but the United Company accepted them at 100 per cent. When the interim dividend was declared in January, 1889, the source of profit upon which they based that dividend was the Elmore shares. He could not say that if the option had not been given up by the Limited Company the United Company would not have been in a position to pay an interim dividend out of realised profits. As a matter of fact, it seemed to be the case that the interim dividend and the new issue were considered at the same meeting; but he resented the suggestion that they were purposely timed to go to the public together. He had no recollection of letters read, signed "A. Grant," and coming in one case from the Phœnix Trust Company, and in another from the National Financial Corporation, relating to projected transactions in the Founders' shares of the United Company. He did not recollect a letter from the auditor recommending the Directors to call in an independent valuer to appraise to value of the shares held in other companies, so as to relieve themselves of responsibility in the matter, and he did not know that an independent valuation ever was made.

By Mr. STIRLING: A committee of shareholders was appointed to investigate the affairs of the United Company, and that Committee issued a report in March, 1892, which the Directors published, together with observations thereon. He was consulted with regard to those observations, and accepted responsibility for them.

By the OFFICIAL RECEIVER: He did not accept responsibility for the issue of the prospectus, although his name was upon it.

The REGISTRAR said it was rather a matter for argument as to whether witness was responsible or not, seeing that he did not join the Board until after allotment.

By Mr. PILLING: He did not discover, as liquidator, that an egregious blunder had been made in the estimate of the profits of Woodhouse and Rawson (Limited). They rather wished they had kept it in their own hands. Certain proportions of the proceeds of the Debenture Stock were distributed amongst the shareholders. He did not admit that the assumed values of the shares were not realised. It would be a wrong statement to say that £100,000 worth of assets were not realised.

By Mr. H. G. RAWSON: He did not think there was ever a question of voting upon matters between the Limited Company and the United Company. He recollected that a time came when it was proposed to dissociate, in the accounts, sums spent in the financial from those spent in the industrial business; but he could not say whether it was proposed to include money spent in testing patents in the industrial part of the accounts, or not. The difference between £16,000, the sums already mentioned as having been spent on the Epstein patent, and £35,000, the sum at which they were valued in the balance-sheet, was by no means clear profit, as there were other expenses connected with the development of the patent which were not specificially mentioned. He could not say that the Okonite Company was one of the few companies successfully floated in the latter part of 1890.

By Mr. F. L. RAWSON: He had had frequent differences of opinion with his questioner as to the course to be pursued in regard to certain matters. He believed that he (Mr. Rawson) in all he did strove for the interests of the shareholders.

By Mr. JENKINS: Witness had, in 1890, chiefly devoted himself to the industrial part of the business, although he attended committee meetings regarding financial affairs. He relied upon the information given him with regard to the value of the shares. He believed all the balance-sheets put forward during his directorate were fair, accurate statements of the affairs of the Company.

Mr. MALCOLM DUNDAS, the first Secretary of the Company, examined by the Official Receiver, said he was quite new to the work when appointed, and worked under the supervision of the Managing Director. The minutes of a meeting of the Directors, held at No. 1, Queen's-gate, the residence of Lord Aberdare, when it was decided to go to allotment, were in his writing, but he was not present at that meeting. At another meeting of the Board, held at Mr. Pope's chambers, in Parliament-street, he was not present, and the minutes must have been supplied to him by someone else. He was not at that time aware that it was an essential part of his duty to attend the Board meetings and record what took place. He was present at the meeting when the questions of the interim dividend and the new issue were discussed and resolved upon, but he could not recollect anything of the discussion which took place.

At this point the inquiry was adjourned until the next day.

THURSDAY, JUNE 28TH.

On the proceedings being resumed yesterday, the OFFICAL RECEIVER said that, with regard to the statement made by Mr. H. G. Rawson as to some of the missing documents, he wished to say that a certain amount of correspondence had been found, and he was quite willing to accept the assurances of the Managing Director that he was making every search; but it was the fact that some most important documents, relating to the valuations, were not forthcoming. He trusted they would be by the end of the examination.

Mr. DUNDAS again went into the box, and, examined by the Official Receiver, said he recollected seeing the circular announcing the withdrawal of Sir John Coode, Sir Albert Cappell, and Col. Howard Vincent; but it was not prepared or sent out by him, though purporting to be signed by him, the initials, however, being wrong.

By Mr. F. L. RAWSON: He (Mr. Rawson) was always anxious to have the minutes accurately recorded. Before becoming secretary to the Company he had had considerable experience in banking, and had since had considerable experience as a secretary. Whilst he was with the Company he considered everything was carefully and properly done so far as he knew.

Lord ABERDARE and Mr. HOSTER, one of the Directors and liquidators of Woodhouse and Rawson, were then examined. The examination of this last witness occupied the whole of the afternoon, and fuller particulars will be given in *The Electrician* next week.

The examination was then adjourned until Thursday next week.

Anglo-American Telegraph Company (Limited) v. Compagnie Francaise du Telegraphe de Paris a New York.

This action, for damages for alleged illegal breaking of a pooling agreement, which has occupied the attention of the various French Law Courts since the beginning of 1887, has reached its last stage.

It will be remembered that on December 31, 1886, the French (or Pouyer-Quertier) Company, acting on a letter received from the French Minister of Posts and Telegraphs, notified the Anglo-American Company of their intention at once to break the "common-purse" agreement entered into in 1880 by the Atlantic Cable Companies. Legal proceedings were taken by the Anglo-American Company, who claimed damages of 2,000fr. a day during the continuation of the rupture, and on January 9, 1888, the Tribunal of Commerce gave judgment in their favour. An appeal was lodged, and on April 24, 1888, the Cour d'Appel ruled that, as the letter of the Minister of Posts and Telegraphs was not quite clear in its terms, recourse must be had to the administrative jurisdiction for an authorative interpretation of its meaning. The Conseil de Préfecture ruled that the P.-Q. Company were justified in breaking the agreement on receipt of the Ministerial dispatch; but the Conseil d'État, on appeal by the Anglo-American Company, decided that the Ministerial letter could not authorise the P.-Q. Company to break a properly-effected agreement between the parties; but that the Company should have applied to the Government for permission to carry out the arrangement made with the Anglo-American Company. Notwithstanding this decision, however, the Minister of Commerce and of the Colonies expressly prohibited the P.-Q. Company from resuming the broken agreement. Under these circumstances, the latter Company entered a fresh appeal from the adverse decision of the Tribunal of Commerce, and this appeal was heard in the Cour d'Appel, before M. Périver, on May 30th, and June 5th, 6th, 7th, 12th, and 26th. Maitres Rodolphe Rousseau and Waldeck-Rousseau appeared for the French Company, and Maitre Barboux for the Anglo-American Company.

On Tuesday last the Advocate-General summed up, and his conclusions were favourable to the Anglo on all points, except as regards the assessment of damages. These conclusions were to the following effect:

I.—*There was no "force majeure" authorising the P.-Q. Co. to break off the Pool Agreements of 1880 and 1882;*

II.—*The persistent refusal of the P.-Q. Co. to carry them out justified the Anglo Co. in asking the Court to cancel them with damages;*

III.—*Damage had certainly been suffered by the Anglo Co., but to what extent was not clearly shown, and therefore it could only be ascertained by a reference to experts.*

The following were his arguments on each of these three propositions:—

I.—NO FORCE MAJEURE.—In the first place (he said) the Ministerial letter of December 31, 1886, did not constitute *force majeure*. That has been decided in the last resort by the Council of State, and, therefore, the question would not be re-opened. In the next place, the Ministerial letter of May 21, 1891 (Jules Roche's), did not constitute *force majeure* either, for the following reasons:—(1) It was a mere opinion, and not a formal decision: (2) If a decision, it was not a decision in the last resort, the P.-Q. Company having a right to appeal, which it was its own fault if it

Digitized by Google

did not exercise; (3) It was contrary to the opinion of the former Minister (M. Cochery). The Advocate-General here went into the facts of the case in order to show that on the P.-Q.'s own admission, nay, on its own assurance as contained in the final agreement of January 17, 1991, M. Cochery considered the Pool Agreement of 1880 as not coming within the meaning of Art. 9 of the P.-Q. Cahier des Charges. He took occasion to point how badly the P.-Q. Company had behaved through, and how richly they had deserved the castigation inflicted upon them by the tribunal, by the Advocate-General, M. Manuel in 1888, and by M. Levavasser de Precourt, the Commissary of the Government at the Council of State.

II.—Necessity to Cancel the Contracts.—This, of course, was a natural consequence of the Advocate-General's argument on the first point.

III.—Damage Suffered, but Amount Unascertainable except by Reference to Experts.—The Advocate-General first of all examined the relative positions of the parties when the first Pool Agreement (1880) was entered into. Upon this point he agreed entirely with the Anglo Company, viz.:—(1) The object of the agreement was, on the part of the P.-Q. a *present*, on the part of the Anglo a *future*, advantage; (2) The P.-Q. Company had held to the agreement as long as it found it to be to its interest to do so; (3) It broke off because it thought it could make better terms with another Company; (4) The other Company was a party, since it lent the P.-Q. Company £40,000 without interest, in order to get the benefit of its cable. The only point, therefore, remaining to be considered, in the opinion of the Advocate-General was the *quantum* of damages. This, he observed, it was impossible as matters stood to ascertain with any degree of precision. The Anglo-American Company had proposed, indeed, different modes of assessment: (1) A return of the £246,000 paid to the P.-Q. Company over and above its own earnings; (2) A fictitious reconstitution of the pool, bringing in the P.-Q. Company a debtor to the extent of £89,066 up to 1892 inclusive, with a reservation as to ulterior damages up to 1920, which he held, contrary to the contention of the P.-Q. Company, to be the date of expiry of the contract. Neither of these two schemes, however, could be admitted. The cause of damage, according to the Advocate-General, arose from the breaking-off of the agreement only, and not from anything that had been done previously. Up to December 31, 1886, there had been no breach of contract on the part of the P.-Q. Company. On the other hand, the Anglo might have paid the P.-Q. £246,000 more than it had earned, yet there was nothing to show that it had not done so out of increased receipts owing to the contract itself. For in that case the P.-Q. Company could show a clear consideration for the money paid. The Advocate-General analysed the tables very carefully and very accurately, and rejected this scheme. At the same time, he treated a counter-table put forward by the P.-Q. Company as altogether unreliable, and, moreover, confessedly so. What, then, should be the criterion? It would be a *bonâ fide* statement drawn up by the P.-Q. Company of all the messages it had carried gratuitously; but as the P.-Q. Company did not seem inclined to do this, there was no alternative but to refer the matter to experts.

It is anticipated that the decree will be pronounced in about a fortnight.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

Tenders Invited.—The Council of the County Borough of West Ham invite tenders for the electric lighting of the Public Hall and Free Library, Barking-road, Canning Town, E. Specifications, &c., may be obtained of Mr. Lewis Angell, borough engineer, at the Town Hall, Stratford, E., and tenders must reach Mr. Fred. E. Hilleary, the town clerk, by four o'clock on July 10th. Further particulars appear in our advertisement columns.

——— The County Borough of Bury invite tenders for the erection of buildings in connection with the electric lighting central station. Tenders must be in to Mr. J. Haslam, town clerk, by six o'clock on Monday next.

——— The Edinburgh tenders for cast-iron road boxes, copper strip connectors, &c., gun-metal grip boxes, cable connectors, and cones have to be in by Wednesday next.

Electric Traction in Egypt.—Our readers are reminded that July 1st is the last day for sending in tenders to the Egyptian Ministry of Public Works for the construction and operation of electric tramways in Cairo.

Tenders Accepted.—The tender of Messrs. Sharp and Kent has been accepted for the electric light installation at the new Grand Theatre, Blackpool.

——— The contract for lighting by electricity the Art Exhibition, to be held at the Blackburn Free Library in August next, has been let to Mr. H. Brennand.

——— The St. Pancras Vestry have accepted the tender of Mr. J. O. Richardson, of Peckham, for the erection of the main buildings, boundary walls, &c., of the King's-road electric lighting station for £5,178.

Sale by Auction.—Messrs. Wheatley Kirk, Price and Goulty announce the sale, by public auction, at the Vulcan Iron Works, St. Neots, of the entire contents of the several works hitherto carried on by Mr. George Bower. The stock includes engines, exhausters, ammonia liquor pumps, gas-holders, and a large quantity of machinery and plant. The sale takes place on July 17th, 18th and 19th, each day at 10, for 11 prompt.

Vacant Appointment.—Applications for the post of Chief Electrical Engineer to the Vestry of St. John, Hampstead, have to be in by Monday next.

Appointments.—Mr. B. J. Diplock has been appointed Secretary of the Fowler-Waring Cables Company (Limited) in place of Mr. D. Stephen, who resumes his duties as accountant of the Company. Mr. James Tiddy, late Manager of the Central and South American Telegraph Company, has been appointed electrician-in-charge of the testing rooms of the Fowler-Waring Company at North Woolwich.

Liquidations.—In the matter of the Collier Audible Telephone Syndicate (Limited), it was stated on Thursday, on the hearing of a petition for its winding up, that arrangements had been entered into for the sale of the assets for a sum sufficient to provide for the costs of the liquidation, and 20s. in the £ to the creditors. The petition was directed to stand over for three weeks, on the understanding that the debt and costs due to the petitioners should be in the meanwhile paid.

——— Creditors of Elmore's French Patent Copper Depositing Company (Limited), whose debts are otherwise than in respect of a debenture or mortgage, must send in particulars of their debts or claims to Mr. J. H. H. Duncan, the liquidator, 39, Coleman-street, London, E.C., on or before the 23rd prox.

Partnership.—Mr. W. H. Massey, of 25, Queen Anne's-gate, Westminster, S.W., has taken into partnership Mr. Vincent S. Allpress. The firm will be known as Massey and Allpress, consulting engineers.

Dissolution of Partnership.—Messrs. Crawshaw and Wray, trading as the Wray Electrical Engineering Company, of Bradford, have dissolved partnership. Debts will be paid by Mr. Cecil Wray.

Removal Notice.—The Edison and Swan United Electric Light Company will, on August 27th next, remove into their handsome new premises, Ediswan-buildings, 36 and 37, Queen-street, Cannon-street, E.C.

Incandescent Lamps.—Messrs. Gabriel and Angenault, who are well known on the Continent, have just opened a London branch at Connaught-mansions, Victoria-street, S.W., for the sale of incandescent lamps which have already obtained a considerable reputation on the Continent. A stock of the lamps sufficient to meet the largest and most varied demands is to be kept.

A Light Motor.—Messrs. Mavor and Coulson have recently supplied the Battery and Motor Company with a 500-watt Sayers motor for 500 revolutions per minute, which weighs under 2 cwt., and has an electrical efficiency of over 90 per cent.

Lighting the Gigantic Wheel.—Messrs. J. G. Statter and Co. have secured the contract for lighting the gigantic wheel at the Earl's Court Exhibition, the contract including the supply and erection of generating plant, the lighting of the 40 cars on the wheel, and the illumination of the wheel itself with 160 lamps. The total installation comprises 280 lamps.

Battery Patents.—Notice is given that it is the intention of the Electric Construction Company (Limited) and the Electrical Power Storage Company (Limited), who are exclusive licensees under the letters patent granted to J. H. Johnson, of 47, Lincoln's Inn-Fields, in the matter of an invention by M. Camille Faure of "improvements in galvanic polarisation batteries or magazines of electricity and the application of the same, and in apparatus connected therewith," to apply for an extension of time for the said letters patent.

New Lamps for Old.—The adaptability of the electric light to oil and candle fittings is strikingly exemplified at the town residence of the Baroness Burdett-Coutts, in Stratton-street, Piccadilly. For upwards of a hundred years this mansion, which contains so many valuable pictures and other art treasures, has been lighted entirely by oil and candles; but these have now given place to the more modern glow lamp. The change presented some difficulties, for it was the express wish of the Baroness and Mr. Burdett-Coutts that in no case should the old fittings be removed, the former sources of light be altered, or the bare filament of the lamps be allowed to meet the eye. The work was placed in the hands of Mr. V. G. Middleton, of Westminster, S.W., and is a satisfactory change from the old to the new. Very beautiful is the effect of the heavy glass candelabra, 16 c.p. lamps being placed behind curtains of glass lustres, and small 4 c.p. lamps, enclosed in cut-glass bulbs, taking the place of the old candles. In the picture gallery light is admitted in the day-time through circular glass lunettes in the ceiling. Glow lamps have been placed above these lunettes, and when alight brilliantly illuminate the whole gallery, at the same time being practically out of sight. In the reception rooms alone there are some 580 16 c.p. lamps, or their equivalent, and some hundreds more in the offices and upper floors. The electrical work was carried out by Messrs. Townsend and McIntyre, and the fittings and glass work by Messrs. Perry and Co., of Grafton-street, W.

MESSRS. BAILY, GRUNDY AND BARRETT (LIMITED).—This Cambridge firm have recently carried out a number of installations of a public and private character.

ABERDEEN.—An extension is being made to Trinity Hall, Aberdeen, by the addition of a minor hall, or upper room, and additional committee rooms and a strong room. The whole of the building is to be lighted throughout by electricity. The Town Council on Tuesday decided that the charge for electric current for the public lighting should be 3¾d. per lamp per hour. The original estimate of the cost of working the electric lighting station, laying down plant, &c., was £25,000; but as only £20,000 was necessary to complete the work then in hand, only the smaller sum was borrowed. It is now found necessary, however, to borrow the additional £5,000, and it has been arranged to do so. A question was asked Mr. Murray, the electrical engineer, as to whether he had advised the putting in of gas pipes in addition to the electric lighting apparatus, which Mr. Murray indignantly denied. There was no necessity for gas pipes to be put into any building where it had been decided to use the electric light; there was absolutely no risk of the electric light breaking down.

BIRKENHEAD.—A Local Government Board inquiry took place on Tuesday as to the application of the Corporation for sanction to borrow the sum of £20,000 for electric lighting purposes, and other monies, the sum being broken up into two amounts of £1,576 for the purchase of land in Bentinck-street for a site for a central station, and £18,424 for the supply and erection of buildings and plant. The Town Clerk explained that possibly the Inspector might withhold his certificate for the latter amount, because at the moment the Corporation had not really approved the plans prepared by their electrical engineer, Mr. Shoolbred. Although the Corporation were not in a position to submit the details, they were practically agreed upon the scheme.

BOOTLE.—The Town Council have decided that the necessary work in connection with the construction of the engine-house, required for the electric lighting installation, shall be carried out by its own borough surveyor, including the alterations to the existing machinery and engine-house.

BOLTON.—The result of the Corporation's decision to supply electric light fittings on the hire-purchase system has been that the applications for electric current have considerably increased.

BOURNEMOUTH.—A Local Government Board inquiry has been held at the municipal offices into the application of the Corporation to borrow £4,000 for electric lighting purposes. There was no opposition. It was pointed out that the Corporation had already erected engines in the pleasure ground for the purpose of pumping salt water, and now desired to utilise the spare power for the purpose of lighting the pier and gardens by electricity, for which they hold a Board of Trade licence.

BRISTOL.—No reply has been received from the Local Government Board as to the application of the Corporation for sanction to borrow £24,650 for the electric lighting extension. The inquiry was held on April 25th last, and the money is urgently required for extensions, several of which are blocked until the Local Government Board's sanction is received.

CALCUTTA.—The electric light is making rapid progress in India for the purposes of mill lighting. A recent installation is at the Calcutta Flour Mills, where Messrs. Kilburn and Co. have erected a Crompton dynamo which supplies the current for 38 incandescents of 32, 16 and 8 c.p. The Oriental Telephone and Electric Company (Limited) opened an electric light department in Calcutta about four months ago, and their Manager, Mr. Lester Betts, has just carried out the initial installation at Messrs. A. C. Mookerjee's Roller Flour Mills.

CHARGE OF FRAUD.—At Bow-street Police Court, on Wednesday, Mr. Lawrence Henry Bloomfield, electrician, of Queen Victoria-street and Richmond, answered to a summons charging him with obtaining by false pretences £120 from Richard Lonsdale. Mr. Purcell, for the plaintiff, said that he wished to withdraw the summons. The facts of the case did not warrant all that was set forth in the information, and there was reason to believe that there had been no intention to defraud. Mr. Vaughan, the magistrate, said that, according to the information, there was a *primâ facie* case, and the matter must be explained. Mr. Humphreys said that, according to the information, the complainant was told by the defendant that he had secured a contract with the Brighton and Hove Electric Light Supply Company. The complainant contended that the defendant had not secured such a contract. As a matter of fact, the defendant had not secured it; but he was in communication with a man named Stevens, who promised to secure it for him. The defendant borrowed money from the complainant for the purpose of buying electric lamps in Germany, and, as a matter of fact, he went to Germany and made purchases there. Mr. Vaughan said that the complainant had better give evidence, and then Stevens ought to be called. The complainant stated that he was an electrical engineer carrying on business in the Strand. Last year the defendant said that he was an agent for a Dutch firm of electric lamp makers, and the complainant agreed to supply him with money for the purchase of lamps. In February last the defendant said that he had secured a contract with the Brighton and Hove Electric Lighting Company (Limited). Believing this to be true, the complainant advanced him £120 to enable him to go abroad and purchase lamps. In reply to the magistrate, the complainant said that the defendant told him he had secured the contract through another man, although he made no mention of that in the information. Mr. Vaughan said that in the face of that admission it would be useless to proceed further. The other man referred to might have made a false statement to the defendant as to the Brighton and Hove contract. There appeared to be no intention to defraud, and the case must be dismissed.

CHURCH LIGHTING.—The Duke of Newcastle announced, at a public luncheon in connection with the Patronial Festival of St. Alban-the-Martyr, Holborn, W.C., that among the improvements for the church the introduction of the electric light was included.

DEWSBURY.—Messrs. A. Hurst and Son have secured an order from Mr. W. Newsome, who has erected a large pile of buildings at the junction of Croft-street and Bond-street, to put down an electric lighting plant for four arcs and 72 16 c.p. incandescents, the plant to include a 6 H.P. gas engine.

DUNDEE.—It is suggested that "if a profit should speedily be obtainable from the Electrical Department it could not be better utilised than in reducing the debt upon the gas works." At the annual meeting of the Gas Commission the financial statement for the year was presented by Mr. James Mitchell, who said that in framing the electric lighting accounts at the beginning of the year they were without data to go upon. It was, however, satisfactory to find that, while the expenditure considerably exceeded the estimate, there was a corresponding increase in the revenue account. They had estimated a receipt of £2,035 from the sale of current and meter rents, whereas they had received £2,649. Their experience in the working of the Electric Light Department was similar to that of other towns, the first few years showing a deficiency, which disappeared on an increased demand for the light. They had a first-class station, and had every reason to congratulate themselves on the success of their electric light undertaking, which would doubtless shortly become a source of profit. They had at present 186 customers, using current equal to 5,293 16 c.p. lamps, and this number was rapidly increasing. An estimated increase of £670 was looked forward to for the current year. Mr. Mitchell concluded the reading of his report by moving that electric current be supplied for the present year at 5d. per unit. ——It has been decided to place the contract for the maintenance of the accumulators at the electric lighting station with the Electrical Power Storage Company, of Great Winchester-street, London, E.C.

ELECTRIC MINING MACHINERY.—An electric drilling machine has been introduced in the Lumpsey mines at Brotton. The machine was tried last week for the first time, and gave every satisfaction.

FAREHAM.—The Local Board on Wednesday last week again considered the question of the purchase of the works of the Fareham Electric Light Company. A letter was read from the Secretary agreeing to the terms suggested by the Board, whereby the Company sell their undertaking to the Local Board for £5,000, and agree to lay underground the electric mains in certain streets, and to provide a new engine, similar to that now in use, for an additional sum of £1,000. After some discussion, it was arranged that, pending the application to the Local Government Board for permission to borrow the necessary loan, the Clerk should prepare a contract for the purchase of the electric works, which would be considered at another meeting of the Board.

FOLKESTONE.—At the last meeting of the Corporation a letter was read from the Brush Provincial Company, asking for the Corporation's sanction to an application for a Provisional Order, and proposing to undertake to bear all expenses in connection therewith. The Corporation were asked to enter into a contract with the Company to light the sea front. The Town Clerk had replied to this letter that the Corporation had not yet abandoned the idea of themselves undertaking the electric lighting of the district. It will be remembered that the Folkestone Corporation, after deciding upon a scheme involving an outlay of £30,000, subsequently quashed this decision, and have now before them an offer made by Mr. Baker to prepare a scheme under which Folkestone is to be lighted electrically at an outlay of £12,000. This scheme, however, has not yet seen the light, and it is on account of this delay that many members of the Corporation are anxious that the Brush Company's application should be granted. It was ultimately decided that a meeting should be called to discuss the scheme to be prepared by Mr. Baker.

Digitized by Google

HAMPSTEAD.—At the meeting of the London County Council, on Tuesday, the Financial Committee recommended a loan of £25,000 to the Vestry of Hampstead for electric lighting purposes, to be repaid in 25 years. The Vestry asked that the term of repayment should be extended to 42 years, as the Council had given its sanction to loans being repaid in that period for similar works by the Vestry of St. Pancras. The Committee were of opinion that the term of repayment should not exceed the life of the works upon which the money was to be expended. After a prolonged discussion the recommendation of the Committee was disagreed with and the request of the Vestry acceded to by 52 votes against 21.

HUDDERSFIELD.—At the last meeting of the Borough Council it was decided to purchase from the Silvertown Company the cable required for the electric lighting works, and a deputation was appointed to inspect, with a view to purchase, a 250-kilowatt Brush alternator, now running at the City of London Electric Lighting Company's Station at Bankside.

KINGSTON.—The Town Council have decided to arrange for the extension of the electric lighting area up the Kingston Hill, round by Queen's-road, and through other principal thoroughfares.

LEEDS.—An offer made by the Yorkshire House-to-House Electricity Company to supply current for any number of arc lamps up to 30 on the line of mains through some of the principal streets in the centre of the City at 4d. per unit, has been declined by the Lamp Committee of the Leeds Corporation, on the ground that a large sum of money has recently been expended in fixing large gas lamps in the principal streets.

LIVERPOOL.—The Liverpool Electric Supply Company have given formal notice to the Watch Committee of the Corporation of their intention to apply for a Provisional Order to supply electricity for public and private purposes in various parts of the city, including Queen-street, Oldhall-street, Devonshire-road, Springfield-street, and the Goree Piazzas.

MADRAS.—The Indian Government are considering a proposal for lighting by electricity the Presidency Post and Telegraph Offices in Madras.

NORTHUMBERLAND COUNTY COUNCIL.—The Committee of Visitors having recommended that the County Lunatic Asylum should be lighted by electricity at an estimated cost of £7,010, but at the last meeting of the County Council carried an amendment to substitute gas for electricity by 21 to 18.

PORTSMOUTH.—Considerable activity is noticeable here in electric lighting matters. The Arts Club has decided to adopt electricity, and the proprietors of several of the principal residences are negotiating.

PROVISIONAL ORDERS.—The amendments made by the House of Lords to the West Hartlepool electric lighting order have been considered by the House of Commons and approved.——The Aberdare Electric Lighting Order, which has already passed the House of Lords, has been certified for second reading by the examiners of the House of Commons.——The Plymouth Provisional Order has satisfactorily passed the Examining Committee of the House of Commons.——The Provisional Order applied for by the Shropshire Electric Light and Power Company has passed the House of Commons Examiner and stands for second reading.——The Bill under which the Bolsover Gas Light and Coke Company seek power to supply electric current within the district has been certified for second reading in the Commons, having passed the House of Lords.

ROYAL AGRICULTURAL SHOW.—The show at Cambridge held during the present week has been, owing to the fine weather and the general excellence of the exhibits, a pronounced success. There is in the exhibits little to interest our readers, except in the Implement Section. The judges appointed in this section include Prof. J. A. Ewing, Cambridge; Prof. D. S. Capper, King's College; and Mr. J. P. Denison, who were appointed to appraise the merits of the various oil engines on show. Amongst the exhibitors in the Implement Section were Messrs. Clarke, Chapman and Co., Crossley Bros. (Limited), W. F. Dennis and Co., John Fowler and Co. (Limited), Leeds; Gilbert Gilkes and Co., Greenwood and Batley (Limited), E. S. Hindley, Ransomes, Sims and Jefferies (Limited), Marshall, Sons and Co. (Limited), Robey and Co. (Limited), and W. H. Willcox and Co. Messrs. Crossley Bros. secured a second prize in Class I. for their 6½-H.P. oil engine. Messrs. Baily, Grundy and Barrett, at Messrs. Crossley Bros.' stand, had on show an Elwell-Parker 90-ampere dynamo driven by a 10-H.P. Crossley oil engine, supplying current to the electric cooking stoves in the Royal Pavilion. These stoves were used for cooking the luncheon to H.R.H. the Prince of Wales, and were in daily use throughout the exhibition. The dynamo also supplied current to a Crompton motor working a Pickering hoist. The cooking utensils used were lined with Messrs. Baily, Grundy and Barrett's new silotena process. Messrs. Robey and Co.'s exhibit included a horizontal steam engine, fitted with their patent automatic trip expansion gear. The engine is specially constructed for heavy work, and is designed for estate work, where by night it can be employed for driving an electric lighting installation. Messrs. Robey's exhibit formed one of the largest on the show grounds and, in addition to their well-known steam engines, included several examples of the Robey oil engine, both of Richardson and Norris's and of Bell, Richardson, and Norris's patents. Of the former description was an 8-H.P. stationary engine, fitted with the latest improved combustion chamber. The special feature of this arrangement is the air inlet, exhaust outlet, vaporiser, and igniter. These engines are built to run equally well with full, half, or light load. There was also on view a 10-H.P. oil engine, the design of which approximates closely to that of the Robey portable steam engine, fitted with a specially-sensitive Becker-type governor, securing great regularity. The working parts are easy of access, and adjustments can be readily effected while the engine is in motion.

ST. PANCRAS (LONDON).—The Electricity Committee of the St. Pancras Vestry having communicated with Messrs. Kelly Bros. regarding the employment of London men in executing the work of building the main central station buildings, that firm stated they could not put themselves under any restrictions as to the men employed, and have withdrawn their tender. Fresh tenders are to be invited.

SHIP LIGHTING.—"La Marguerite," the new palace steamer of the Victoria Steamboat Association, which made its trial trip from London to Boulogne on Saturday last, is lighted throughout by electricity, the work upon this, as upon other boats of the Association, being carried out by Mr. William Mackie, of Turk's Head-yard, E.C.

——— Messrs. J. H. Holmes and Co., of Newcastle-on-Tyne, have lately fitted the steamer "Petersburg," built by Messrs. Hawthorn, Leslie and Co., with an electric lighting and ventilating plant. The lighting plant is adapted for 300 16-c.p. incandescents, and the ventilating plant for six electro-motor fans. The fittings throughout the ship are of very handsome design, and in the emigrant quarters are detachable; so that, if room is required for cargo, they can be speedily removed, the wiring being so arranged that no risk of fire is incurred with these detachable fittings when out of use. The electro-motor fans are the largest yet used in ship ventilation. A 10-hours' test proved that everything had been satisfactorily arranged. Portable electric fans are provided for the saloon.

SUNDERLAND.—The Local Gas Company has informed the Highways Committee of the Corporation that a condition would be imposed under the new contract for lighting the streets by gas, that in cases where gas lamps are supplanted by electric lamps a payment of 10s. would be demanded from the Corporation for each gas lamp discontinued. If electric lighting were installed in any gas area the Company would discontinue to light the 600 c.p. Sugg gas lamps in such area.

THEATRE LIGHTING.—The Directors of the Alhambra, London, have recently adopted the electric light throughout for their stage work. The installation has been designed and carried out by Messrs. F. W. Henton and Co. By the arrangements now adopted gas, calcium lights, &c., are entirely dispensed with.

TUAM.—The local Electric Light Company have notified the Local Board that they intend to apply to the Board of Trade for a Provisional Order for lighting the town by electricity.

WINDSOR.—Sir H. D. Gooch has instructed the Windsor branch of Roger Dawson (Limited) to instal the electric light at Clewer Park. About 100 incandescents will be required, and the plant will include a steam engine and a battery of accumulators.

WOLVERHAMPTON.—The Directors of Thomas Parker (Limited) have accepted the tender of Mr. H. Lovatt, of Wolverhampton, for the erection of their new works on the Wednesfield-road.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

June 7, 1894.

11,069. A. MUIRHEAD. London. Improvements relating to the transmission of signals through submarine telegraph cables.

11,100. F. N. DENISON. London. Improvements in electric dental motor apparatus.

June 8, 1894.

11,123 B. W. WELLS and M. MARTIN. Glasgow. Electro protective system for locks.*

11,136. R. WOOD. London. Improvements in the regulation of electric distribution systems.

11,160. H. W. RAVENSHAW and Messrs. EASTON, ANDERSON, AND GOOLDEN (Limited). London. Improvements in apparatus for starting electric motors.

Digitized by Google

June 9, 1894.

11,211. W. Grimes. London. Improvements in railway electrical signalling apparatus.

11,219. C. A. Hussey. London. Incandescent electric lamp and sockets therefor.*

11,225. H. Bevis and H. Hirst. London. Improvements in and relating to arc electric lamps.

11,241. F. R. Boardman. London. An improved electric lamp.

SPECIFICATIONS PUBLISHED.

Note.—All Specifications can now be obtained at the uniform price of 8d. each.

1893.

4,106. Epstein. Secondary battery plates.

10,398. Lenox. Electrical communication with vessels or buoys.

10,441. Hughes (De Voe). Conduit Electric Railway.

10,569. Crompton and Dowsing. Regulating the temperature of electrical heating, &c., apparatus.

11,426. Todd and Lewis. Electric motor.

12,153. Waterhouse. Measuring, &c., electric currents.

12,362. Armstrong and others. Marking meat by electricity.

12,523. Wollaston. Electric brushes, &c.

13,336. Hoeffner. Electrolytical production of nickel, &c.

13,412. Conrady. Electric generators.

14,091. Brain. Electric fuses.

14,202. Pyke and Harris. Dynamo-electric generators and motors.

1894.

139. Callender. Telephone exchange systems.

5,663. Kleine and Lindner. Cut-offs for gas, electric, &c., conduits.

6,742. Siemens Bros. and Co. (Limited), and Grimston. Electric switch.

8,043. Wyman and Goodwin. Insulating cleat for supporting electric conducting wires.

8,149. Lake (Van Vleck and another). Electrical measuring instruments.

COMPANIES' MEETINGS AND REPORTS.

Electric and General Investment Company (Limited).

The fifth ordinary general meeting of the shareholders in this Company was held at Winchester House, Old Broad-street, on Tuesday, under the presidency of Mr. George Herring.

The SECRETARY (Mr. J. Cecil Bull) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN said: As the attendance of shareholders is not very large, I do not think I need go through too much of the report. I believe we shall all agree upon one thing—that large dividends and small speeches are infinitely better than large speeches and small dividends. The profit and loss account shows a gross profit to the amount of £10,735, including the balance of £65. 16s. 5d. brought forward from last year, and we pay you now in dividends £7,000, leaving £369. 10s. 4d. to be equally divided (according to our articles of association) between the Founders and the Ordinary shareholders. We have also provided for contingencies the sum of £8,000, and I think that when you see by the footnote in the balance-sheet that there is a contingent liability amounting to £35,000 odd, you will agree with me that this is a proper thing to do. At the same time, I may comfort you with this statement—that we have no reason to fear; and although we are certain that this liability will be called up, yet we feel almost as certain that the shares for which there is this contingent liability will be well worth the money, and more too. I will now go to the balance-sheet. The capital, authorised, subscribed, and called up, is the same as before. The reserve fund remains the same. The provision for contingencies I have mentioned. The loan account is money borrowed from the bank. The sundry creditors are the usual ordinary creditors of a company like this, and some of them are already paid. The item of "unclaimed dividends" explains itself, and the balance of profit and loss account I have already mentioned. Now we come to the most serious point—"investments at cost." We have kept the entry in that way, but I can safely say—and I am happy to see the auditor present—that the investments at cost price could be realised even in these depressed times for this amount and more. Speaking for myself, I should be only too glad to give this amount for them now, and therefore I consider that we may rest perfectly assured that we are in a good position with regard to this matter. The sundry debtors, amounting to £918, are quite good, and cash in hand speaks for itself. I will now go to the profit and loss account, and on the one side you see the general charges, including the different items of which the amount is made up, and the additional remuneration which the Directors get after paying a dividend of 10 per cent. These general charges amount to £2,365. The interim dividend which we paid was at the rate of 10 per cent. per annum, leaving the net profit available as before mentioned. On the other side of the account you see the amount of our receipts, and we only carry down what we really consider the profit for the time being. I do not think I shall have many questions put to me, but I shall be only too happy to answer them. I now propose—

"*That the Report of the Directors and the statement of the accounts to May 31st, 1894, with the appropriation of the surplus profits as proposed, be and the same are hereby received and adopted.*"

Mr. J. B. BRAITHWAITE, jun., in seconding the motion, remarked that the shareholders would see that the Company was getting into a very sound condition. They now had a reserve fund amounting to the whole of their paid up capital.

The resolution was carried unanimously.

The CHAIRMAN then proposed—

"*That a Dividend at the rate of 40 per cent. per annum for the half-year ended May 31st, 1894, making with the interim dividend of 10 per cent. paid for the six months ended November 30th, 1893, 25 per cent. for the year, be and the same is hereby declared on the capital paid-up on the Ordinary Shares, that a dividend of £30 be declared on each Founder's Share, and that the respective dividends be paid on June 27th, 1894.*"

Mr. B. H. VAN TROMP, in seconding the motion, said it must be a great satisfaction to all the shareholders to know that the Company had been so well conducted that they were able to pay the dividend proposed out of the profits they had made, and with perfect fairness towards everyone.

The resolution was carried unanimously.

The Right Hon. Lord CLONCURRY then proposed the re-election of the retiring Directors, Messrs. Herring and Van Tromp. He was, he said, sure that the shareholders would unanimously pass the resolution, for their success was mainly due to the unremitting attention of the Chairman.

The MANAGING DIRECTOR (Mr. Emile Garcke) seconded the motion, which was unanimously adopted.

The auditors, Messrs. Rait and Kearton, were afterwards re-elected for the year ending May 31st next.

The proceedings then terminated.

Reuter's Telegram Company (Limited).

The thirtieth ordinary general meeting of this Company was held on Wednesday, at the offices, Old Jewry, Admiral the Right Hon. Sir J. C. D. Hay, Bart., K.C.B., presiding.

The SECRETARY (Mr. W. F. Bradshaw) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN then said: Gentlemen, I now rise to move the adoption of the report, and I may explain why the general meeting has been held later than usual this year. The reason is that since the opening of our advertisement business it has been found difficult to present the accounts so early as was the case before the commencement of the advertisement business, and even last year and the year before it was with difficulty that the accounts could be furnished at the end of May. In view of this circumstance it was thought advisable to simplify matters by postponing the general meeting for a few weeks, by which the advantage has been gained of being able to meet the shareholders after all arrangements with Reuter's International Agency have been finally completed and legally settled. In future, we hope to revert to an earlier date for our general meeting. The advertisement business having been discussed at the recent special general meeting, my remarks on this occasion will be directed to the other branches of the Company's operations. I wish we were able to present to you a more favourable report. I believe, however, that you will not be wholly unprepared for the statement I have to make, in view of the fact that during the whole of last year business continued in a state of the greatest depression. Like so many others, we have been adversely affected by the fall in silver. The subscriptions to our various news services in India, the Straits and China being paid in silver, we have lost considerably by the decline in the value of the rupee and dollar respectively. The loss due to this cause will be apparent when I remind you that the difference between 1s. 6d. a rupee, the rate current when our contracts were entered into, and the actual rate means a loss to us in India and the Straits alone of about £2,000 per annum. The partial paralysis of trade arising from the same cause has reacted on our business in other departments. We did not fail at once to make the necessary changes, and hope that the fresh arrangements will improve our position before the end of this year. You will readily understand the large outlays rendered necessary by the protracted civil war in Brazil, the troubles in Argentina, and the Matabele campaign, not only in telegrams, but also in obtaining the information embodied in those telegrams. The accuracy and promptitude of our service regarding these matters have been generally recognised, and I am happy to be able to inform you that to-day we enjoy a larger measure of support from the Press than we have done at any previous period of our history. This shows that our business is sound; and, but for the causes previously explained, and over which we had no control, the results for 1893 would have been more favourable. While on the subject of our news business I should like to state that we were put to a great deal of unexpected expense last year, owing to the action of a news organisation in the United States with whom we had a contract for some time. We have been saddled with heavy outlays, which considerably swell the amount figuring in the accounts under the head of expenses. This matter is now before the Courts, and I will only say that we hope to obtain compensation for the loss we have sustained. Our present arrangements in America are most satisfactory, and we are on the closest terms of alliance with the Associated Press. In conclusion, I beg to move "That the report and accounts now presented be received, adopted, and entered on the minutes."

The Hon. MARK F. NAPIER, M.P., seconded the motion, which was carried unanimously.

Baron GEORGE DE REUTER proposed, and Mr. FREDERICK J. GRIFFITHS seconded, the re-election of Admiral the Right Hon. Sir J. C. D. Hay as a director.

The motion was carried, and after the re-appointment of Messrs. Welton, Jones and Co. as auditors, the proceedings terminated.

Hobart Electric Tramway Company (Limited).

The first annual general meeting of the shareholders was held at the offices of the Company, College Hill Chambers, Cannon-street, on Wednesday last, Mr. D. J. Mackay presiding.

The SECRETARY (Mr. G. Carnaby Harrower, C.A.) read the notice calling the meeting, the report of the Directors and statement of accounts being taken as read.

The CHAIRMAN said: Gentlemen, at the first ordinary general meeting of the Company, which was held on June 30, 1892—nearly two years ago—Sir Edward Braddon, who presided, detailed the circumstances that attended the formation of the Company, and sketched out our prospects as they at that time appeared. Since then we have passed through a financial crisis of unprecedented magnitude, which has, in greater or less degree, affected all the Colonies. The crisis did not directly affect our Company, as the funds for the completion of the tramway had been provided at its formation; but it is probable that our traffic receipts have been affected by the altered financial conditions in the Colony. It is fitting that, in the first place, I should explain the cause of the protracted delay that has occurred in presenting our report, which you will see is for a period of about twenty-one months. The Company was registered on March 4, 1892, and our report is for the period to December 31, 1893. You will recollect that under the contract with the original Company it was provided that the vendor Company should complete the lines to the satisfaction of this Company, and hand over the same in time to enable Messrs. Siemens to commence the running by January 1, 1893; and by the contract with Messrs. Siemens it was provided that the lines would be open for public traffic by that date. Instead of opening the line upon this date we were unable to do so, as the report shows, until September 21st following. Messrs. Siemens were unable to deliver a portion of the plant on account of a strike at the works of one of the contractors. After the plant had arrived in Tasmania a difficulty arose with the Government, at the instance of the local telephone company, who alleged that the service would interfere with their service. This difficulty proved to be serious, and involved protracted delay; but eventually it was amicably adjusted, under an arrangement by which our wires were placed so as not to interfere with those of the telephone company. The suspension of operations was a serious matter to us, as meantime our debenture interest had to be provided, and no revenue was being received. The service was opened on September 21st, and the tabulated statement in the report (given below) shows with what result, there being a considerable surplus after providing for maintenance charges. This surplus would doubtless have been larger but for the fact that the full service was not supplied at the start. It is only natural to expect troubles to arise at the commencement of running; but I am pleased to be in a position to announce that the service is now fairly well maintained, and that when we see our way to provide the additional sidings required we shall be in a position to fulfil the expectations held out in the prospectus as to the extent of the service. In the report you will observe reference is made to the settlement with Messrs. Siemens of the amount due under their contract, and it is right that I should allude to this matter. Messrs. Siemens, under their contract, were to hand over the line in working condition with a full service by December 31, 1892, but the difficulties to which I have referred prevented this being done. We accordingly intimated a claim to Messrs. Siemens for loss of revenue for the nine months beyond the contract date. Messrs. Siemens put forward a counter-claim for loss occasioned to them by our not providing them with way-leaves as set out in the contract. After many meetings we adjusted a settlement on the basis of their being paid the balance due under their contract but no extra charges, on condition that we departed from our claim for loss of revenue. Under Messrs. Siemens' contract they undertook to work the line for 12 months from December 31, 1892, at 4d. per car mile, receiving not less than £1,000 per month, including in same wages of conductors, drivers, and of all the necessary maintenance staff. By a subsequent arrangement with Messrs. Siemens they undertook to work the line to March 31st last, on which date we took the maintenance into our own hands, having with Messrs. Siemens' concurrence entered into an arrangement with their Mr. Parker to supervise the running. Under this arrangement we know that there will be a considerable annual saving. We consider ourselves fortunate in having secured the services of Mr. Parker, who acted as Messrs. Siemens' engineer during the period of construction. Referring to the balance-sheet, there are one or two items which you will probably expect me to explain. The debenture debt is stated at £41,760, but the amount provided for was £45,000. The balance of the issue has since been allocated. These bonds are terminable, being redeemable January 1, 1906, at 105, or at any time during their currency on six months notice. There is also an option to exchange into Ordinary shares at par. Provision will require to be made for the redemption of the issue, and the matter is one that will require the consideration of the Board during the current year. As the bonds carry interest at 5 per cent. the suggestion has been made that in the event of our requiring to make a further issue for extension of mileage and addition to plant, we should be able to replace the present debt by an issue of Debenture Stock at a lower rate. From such an issue advantages would accrue to both the bondholders and the Company. If the bondholders converted they would receive their equivalent in the new Stock, which would have the advantage of a readier market, while we should have our debt on a permanent basis and at a lower annual charge. This suggestion is one which will receive the careful consideration of the Board. On the debtor side "sundry creditors, £1,215," consists mainly of the balance due to Messrs. Siemens for maintenance (£750), the other items being engineers' fees £218, and trusteeship for debenture-holders, income-tax on debenture interest, and auditors' fees, &c., &c., £247. The item, "Balance claimed by vendors," is in dispute. We await further information in regard to this item, and meantime it has been placed in suspense. The items on the other side of the account, representing expenditure in London and Hobart, explain themselves. They represent the charges extending over a period of 21 months. You will observe that no revenue account has been submitted. We propose that all payments and receipts to December 31st be put to capital account, and that the revenue account shall commence as at January 1st, when it might be held that the Company had really made a start. In next year's accounts a profit and loss account will be submitted. You will probably now consider that I have entered with sufficient fulness into the various matters referred to in the report. It is gratifying to be able to state that the interest on the debentures has been regularly paid up to date, and that funds are in hand for the service of the coupons due July 1st. Before I sit down I would refer to the fact that Sir Edward Braddon, the late Chairman of the Company, having returned to Hobart, has been elected to a seat on the Committee there. This reduces the number of the London Board to three, with a corresponding reduction in the fees payable to the London Directors. We desire to carry on the business economically and efficiently, and we hope that the arrangements we have now adjusted to this end will show results which you will consider satisfactory when we submit our next accounts. The cars and electrical machinery have given entire satisfaction to our Local Committee and the public of Hobart, and our electric tramway is one of the features of attraction in Tasmania. We, of course, regard the undertaking mainly from a commercial standpoint; but if to this is added, as in our case, the being the first to demonstrate in the Southern Hemisphere—at any rate, in the Australian Colonies—the advantages of electric traction, the interest in our enterprise is naturally enhanced. Your Directors trust when we next meet we shall be able to congratulate ourselves upon the possession of a successful commercial enterprise. I now move the adoption of the report and balance-sheet, and shall be glad to answer any inquiries you may find it necessary to make.

Dr. A. MATTEI seconded the motion, which was unanimously agreed to.

On the motion of Dr. MATTEI, seconded by Mr. STEWART, Mr. Charles Barclay and Sir Edward N. C. Braddon, who retire at this time, were re-elected.

The auditors, Messrs. C. N. Read, Son and Co., having been also reappointed, the proceedings ended with the passing of a vote of thanks to the Chairman and Directors.

The following tabular statement given in the Directors' report shows the mileage, the takings, and the working expenses (not including those of administration) from September 21, 1893, (opening of line), to March 31st last.

Month.	No. of cars employed.	No. of car miles.	Gross takings.	Working expenses paid or due Messrs. Siemens under contract.	Balance left.
Sept. 21—Oct. '93	483	30,450	£1,618	£1,190	£428

NEW COMPANIES, STATUTORY RETURNS, &c.

ELECTRIC NOVELTY SYNDICATE (LIMITED).—This Company was registered on June 23rd, with a capital of £4,500, in £1 shares, to acquire an invention for "improvements in electrical toys," also an invention for an electrical appliance or apparatus for indicating the names of stations on railways, to acquire all improvements on the said inventions, and any other inventions connected with the manufacture of electrical apparatus, to adopt an agreement dated June 19th between Richard Myers and Edward Nicholls (on behalf of the Company), and to carry on the business of manufacturers of, and dealers in, electrical or other mechanical toys, electrical batteries, apparatus and appliances, electricians, mechanical engineers, suppliers of electricity, and the general business of an electric light company in all or any of its branches.

EYLAND AND SONS (LIMITED).—This Company has been registered with a capital of £15,000 in £5 shares, to acquire the business of opticians, &c., hitherto carried on by Eyland and Sons at Walsall, Staffordshire, and to carry on and extend the same.

FRASER AND FRASER (LIMITED).—This Company was registered on June 23, 1894, with a capital of £30,000, in £10 shares, to acquire and take over as a going concern the business carried on at the Railway Works, Bromley-by-Bow, London, E., and to carry on the business of steel makers, iron and steel converters, and manufacturers, mechanical engineers, electrical engineers, tool makers, tin-plate makers, boiler makers, metallurgists, consulting engineers, &c.

J. AND E. GLEDHILL (LIMITED).—This Company has been registered with a capital of £4,000 in £50 shares, to acquire the good-will of the business of contractors' engineers, hitherto carried on at Lindley, near Huddersfield, and elsewhere, by J. and E. Gledhill.

LIVERPOOL RUBBER COMPANY (LIMITED).—This Company has been registered with a capital of £123,117. 10s., divided into 6,605 Five per Cent. Non-Cumulative Preference shares of £3. 10s. each and 20,000 Ordinary shares of £5 each, to enter into and carry into effect an agreement between the Liverpool Rubber Company (Limited) and Henry G. Tippet (its liquidator) and this Company, and to carry on the business of india-rubber manufacturers in all its branches.

NORTHERN ENGINEERS' SUPPLY COMPANY (LIMITED).—This Company was registered on June 19th with a capital of £3,000, in £5 shares, to supply goods and articles to ironfounders, mechanical engineers, mill-

Digitized by Google

wrights, tool makers, brass founders, machinists, ship owners and builders, railway and canal companies, &c.

PATENTS (PIONEER) SYNDICATE (LIMITED).—Among the objects of this Company, which was registered on June 20th with a capital of £10,000, in £1 shares, is the carrying-on of the business of civil, mechanical, electrical, and general engineers.

SALISBURY ELECTRIC LIGHT AND SUPPLY COMPANY (LIMITED).—This Company was registered on June 21st, with a capital of £20,000 in £1 shares, to carry on in the City of Salisbury the business of manufacturing and supplying electric current, light and power, to endeavour to procure a license from the Board of Trade under the Electric Lighting Acts, 1882 to 1888, and, further, make due application for a Provisional Order under the said Acts, and to carry on any business in connection therewith which the Directors may consider desirable. The subscribers (with one share each) are:—William H. Gramshaw, William M. Hammick, J.P., William Marlow, J.P., Douglas J. K. Macdonald, Arthur R. Malden, Alfred R. Dawson, and Arthur J. Dempsey. The first Directors are to be appointed by the subscribers to the Memorandum of Association.

AMERICAN RIVER ELECTRIC POWER SUPPLY COMPANY (LIMITED).—In reply to official inquiries the secretary stated on June 4th that the Directors of the concern did not proceed to allotment, and all the money was returned to the applicants for shares.

BRITISH INSULATED WIRE COMPANY (LIMITED).—The annual returns of this Company, made up to June 28, 1893, and March 28, 1894, have been recently filed. The nominal capital is £110,000, divided into 300 Founders, 3,950 Preference, 9,450 Ordinary "A," and 8,300 Ordinary "B" shares of £5 each. 300 Founders, 3,770 Preference, 6,902 Ordinary "A," and 7,053 Ordinary "B" shares have been taken up, of which 219 Founders, 975 Preference, 475 Ordinary "A," and all the Ordinary "B" shares have been issued as fully paid. Upon 81 Founders, 2,695 Preference, and 6,327 Ordinary "A" shares the full amount has been called, while upon 100 Preference and 100 Ordinary "A" shares calls amounting to £3. 15s. per share have been made, realising £46,270. An agreement, dated April 20, between Felten and Guilleaume, of Mülheim, Germany, and this Company, provides for the grant of the sole and exclusive licence for making, using and vending, in the United Kingdom and the Isle of Man electric cables, in accordance with an invention for improvements in electric cables, dated April 12, 1892, and numbered 7,029, in consideration for the allotment to the former or their nominees of 1,000 Ordinary "B" shares, which shall be deemed for all purposes to be fully paid up. During the continuance of the licence a royalty of 5 per cent. on the selling price of all electric cables manufactured, used, sold, or otherwise disposed of, from April 1, 1894, is to be paid.

BROWETT, LINDLEY AND CO. (LIMITED).—The annual return of this Company made up to May 2nd has been filed. Out of a nominal capital of £20,000, divided into 1,600 Ordinary and 400 Preference shares, 1,362 Ordinary and 200 Preference have been taken up, of which 800 of the former class have been issued as fully paid. Upon the remaining 562 Ordinary and 200 Preference shares, the full amount has been called and paid.

CALLENDER'S BITUMEN TELEGRAPH AND WATERPROOF COMPANY (LIMITED).—The annual return of this Company, made up to June 5th, has been filed. 6,316 shares have been taken up out of a nominal capital of £80,000, in £10 shares. 3,000 of these have been issued as fully paid, and the full amount has been called on the remainder, resulting in the total payment of £33,160.

CAMBRIDGE UNIVERSITY AND TOWN ELECTRIC LIGHTING COMPANY (LIMITED).—A letter dated May 10th, from Messrs. Baily, Grundy and Barrett (Limited), electrical engineers, of 2, St. Mary's-passage, Cambridge, states that the above-mentioned Company has never made any allotment of its shares, or commenced to carry on any business. It has a nominal capital of £50,000, in £10 shares, and the seven signatories' shares are the only ones taken up.

MOSLEY AND COMPANY (LIMITED).—This Company has just entered into an agreement with Matthew A. Mosley, Robert Wright, and John H. Richardson, all of Wakefield, Yorks, for the acquisition of an invention connected with "improvements in or appertaining to the electro-deposition of zinc," for which provisional protection had been granted. The consideration for the same was fixed at £8,000, payable by the allotment of 8,000 fully paid shares, and 15 per cent. of the net proceeds realised by the Company from the sale or working of the foreign patents.

RAILWAY ELECTRIC READING LAMP COMPANY (LIMITED).—The first annual return of this Company, made up to January 12, 1894, was recently filed. Only the seven subscribers' shares have been taken up out of a capital of £100,000 divided into 16,000 Ordinary and 4,000 Deferred shares of £5 each, and no calls have as yet been made.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend on the Preference shares of the Company at the rate of 6 per cent. per annum for the six months ended the 30th inst., the dividend to be payable on and after the 19th prox.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announce that, subject to final audit, the accounts show, after placing about £110,000 to reserve fund, a balance available sufficient to pay at the general meeting on July 12th next, the fixed dividend of 3s. per share, being at the rate of 6 per cent. per annum on the Preference shares, less income tax, and a final payment of 2s. 6d. per share with a bonus of 3s. per share, both free of income tax, on the Ordinary shares, making with previous payments on account, a total distribution of 6½ per cent. on those shares for the year ended March 31, 1894. The transfer books will be closed from July 4th to 12th inclusive.

CITY NOTES.

BIRMINGHAM MINT.—The Directors of this Company at their last meeting announced the payment of a dividend of 7 per cent. on the share capital for the past year.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended June 24th were £863 as against £765 in the corresponding period of 1893, being an increase of £98. The total receipts for the half-year amount to £22,616, as against £21,799 for the corresponding period of 1893, an increase of £817.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The Directors of this Company on Wednesday declared an interim dividend, for the quarter ended March 31st last, of 2s. 6d. per share, free of income-tax, payable on the 16th prox. The Share Register will be closed from the 7th to the 14th prox., both days inclusive.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—This Company notify that the coupons due on July 1st prox. on their Five per Cent. Mortgage Debentures will be paid on and after that date at the banking house of Messrs. Barclay, Bevan and Co., 54, Lombard-street, E.C.

ELECTRIC AND GENERAL INVESTMENT COMPANY (LIMITED).—The warrants for the dividends on the Ordinary and Founders' shares in this Company, recently declared, have been posted.

ELECTRIC TRANSMISSION OF POWER IN MINING.—The Chairman of the Lisbon-Berlyn Company (Limited) at a meeting of the shareholders on Monday last referred to the plant recently put down for providing motive power at the Company's Frankfort mine. This, he explained, was at present inadequate, but at the Lisbon and Berlyn property, situate about ten miles from Frankfort, the Company had all the motive power it required, and by means of electric transmission they would be able to drive their stamps at the Frankfort. At the Lisbon-Berlyn property they had a waterfall of over 400ft., or nearly three times the height of Niagara. They had proved the value of their property, and it was necessary, in order to enable them to increase their output, to put down at once an electric installation, the estimate for which was £6,600, but which would ultimately amount to about £10,000.

ELEKTRICITATS-AKTIEN-GESELLSCHAFT VORM. SCHUCKERT AND CO.—For the year 1893-94 this Company has a credit balance of 2,103,934 marks, out of which it is proposed to pay a dividend of 9 per cent., and to carry forward 463,663 marks.

ELEKTRICITATS-AKTIEN-GESELLSCHAFT VORM. W. LAHMEYER AND CO.—This Company's balance-sheet for 1893-94 shows the receipts for the year to have been 215,358 marks, while the total expenses have reached 258,059 marks, leaving a deficit of 42,701 marks.

FRENCH COPPER COMPANIES.—It is announced in *L'Industrie Électrique* that the French Elmore Company and the Compagnie Française des Métaux are to be amalgamated, with a capital of 25 million francs. This, if correct, will give M. Secrétan the renewed control of the French copper market.

HOBART ELECTRIC TRAMWAY COMPANY (LIMITED).—Notice is given that the interest due on coupon No. 5 of the First and Second Mortgage Debentures will be payable at the Commercial Bank of Scotland, 62, Lombard-street, London, E.C., on and after July 1st next.

INDIA-RUBBER, GUTTA-PERCHA, AND TELEGRAPH WORKS COMPANY (LIMITED).—A half-yearly general meeting of the Company will be held at the Cannon-street Hotel, London, on Thursday next, the 5th prox., at 12 noon, for the purpose of obtaining the sanction of the shareholders to the payment of an interim dividend of 5 per cent., or 10s. per share, free of income-tax. The Company's Share Register will be closed from the 27th inst. to the 5th prox., both days inclusive.

INTERNATIONALE ELEKTRICITATS-GESELLSCHAFT IN WIEN.—A dividend of 6 per cent. is proposed on the working for 1893-94, against 5½ per cent. paid in the preceding year.

IRISH TRAMWAYS.—The Cork Tramways Company (Limited) invite applications for 1,700 shares of £10 each, £5,000 of which has already been subscribed by the Great Southern and Western Railway Company and some of the leading citizens of Cork. The money is required to construct tramways of a total length of about 3½ miles, with power to work by electricity or horse-power.

ORIENTAL TELEPHONE AND ELECTRIC COMPANY (LIMITED).—The first ordinary general meeting of this Company will be held on Wednesday, July 4th, at one o'clock p.m., at Winchester House, Old Broad-street, E.C.

SALT LAKE AND OGDEN GAS AND ELECTRIC LIGHT COMPANY (LIMITED).—The Gas, Water and General Investment Trust notify that the coupons of this Company's First Mortgage Six per Cent. Bonds due July 1st next will be paid at the National Provincial Bank of England, Bishopsgate-street, on and after July 2nd.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee appointed Wednesday last a special settling day in the Ordinary shares, Nos. 1 to 20,000, of the County of London and Brush Provincial Electric Lighting Company (Limited). They have ordered the further issue of 8,180 Seven per Cent. Cumulative Preference shares, Nos. 20,001 to 28,180, of Crompton and Co. (Limited) to be quoted in the Official List.

SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—An extraordinary general meeting of this Company will be held at the Cannon-street Hotel, E.C., on Tuesday, July 3rd, at 12 o'clock, for the purpose of discussing and confirming the resolution passed at the extraordinary general meeting held on the 14th inst.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended June 22nd (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £2,401.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 842.—Vol. XXXIII. FRIDAY, JULY 6, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/*

NOTES.

Not the least strange of life's many little ironies is the exceeding infrequency with which institutions founded under the most favourable auspices, and with the most benevolent intentions, inure to the benefit of those whom the founders had in mind. But if the demon of misdirection can be exorcised, the clear-sightedness and self-abnegation shown by Mr. Ludwig Mond in endowing the Royal Institution with a "Davy-Faraday" laboratory for the purposes of physical chemistry research should accomplish this feat. Mr. Mond, in modestly refraining to connect his own name with this munificent tribute to pure science, in clearly defining its scope, and in connecting it with the classic names of Humphrey Davy and Michael Faraday, has done all that lies within the power of a single individual to insure that sound work, sober work, and genuine scientific work shall be the fruits of his free-will offering. May the new laboratory be instinct with the spirit as well as honoured with the titles of Davy and Faraday!

We regret to record an accidental death at the Blackfriars transformer sub-station of the London Electric Supply Corporation. The four mains from Deptford enter by a small cellar under the sub-station, and are connected by omnibus bars and switches to the outgoing mains to London. The inner conductors alone are connected to the bare metal-work of the switches, the outers are all connected together by well-insulated cables, and, under ordinary circumstances, no serious shock can be obtained in this cellar, the floor of which consists of a rubber-covered platform on oil insulators. A leak had been discovered on one of the London mains, and this main was cut out by switches, and was tested. It was decided to connect a Deptford main on one side of the cellar to a London main on the other side by two plugs and a length of cable as a temporary expedient. The switch-man, who was thoroughly familiar with his work, and who had been in the employ of the Company for five years, put the plug on to one of these mains, which, according to the strict rules of the Corporation was, while work was being done upon it, "dead." Thinking that the plug might slip off, he used some binding wire to fasten it, and sent his mate for more. It is supposed that the loose end of the binding wire flicked against the "live" omnibus bar about one foot above the plug, and that he thus received a shock, throwing him back. Unfortunately, he had left open a wooden bar protecting the terminal of the faulty main behind him and this allowed his head to strike a live Deptford terminal and at the same time the faulty London main. A serious arc was struck, blowing the fuse at Deptford, and of course killing the unfortunate man. Of the two accidental causes, the use of binding-wire where a bit of string or spun yarn would have sufficed, if, indeed, it were wanted at all, seems to be the more important. No need is apparent; but this man, after five years' experience, must have had some reason. The general arrangement of the sub-station proper, its substantial switching gear, admirable cleanness, and orderliness show that both the Corporation and its staff have done, and do, all that is possible to carry out the work in the best possible manner.

It is not the fashion for the weak to go to the wall; a few feeble folk join together and form a party; this is a species of socialism. Another plan is to choose a strong man and to lean up against him. The ventilation of the Underground Railway could not be tacked on to any political clique, and the obvious alternative was to worry the Board of Trade. Mr. Bryce will soon be asked to arrange that the thermometer shall not exceed 82° in the shade, except on Saturday afternoons and Sundays. The newspaper correspondents who have been busily inventing partitions to divide the tunnels seem never to have investigated the atmosphere of the City and South London Railway, where their ideal is completely carried out. They are, of course, oblivious to the fact that the tunnels would have to be widened and the lines separated to make their brattices practicable. The only cure is to use electric traction, and even this, judging by the South London line, will probably fail to be complete. But we are hardly ready yet for this equipment. It is not a problem for tramway electricians, but must be solved by men like Mr. Greathead, with the assistance of the most experienced contractors. The City and South London line was a very valuable experiment, the Liverpool line is a perfect success, the Waterloo and City line, for which a coffer-dam is now in construction near Blackfriars Bridge, will be built on the experience of these, and will be followed shortly by the Central. London Railway. After that is running the next step should be to see what can be done for the old Underground Railway. But who will compensate the sufferers from hay fever and asthma, who at present find that a few minutes in the darkness and the sulphur and coke-dust-laden air gives a relief that nothing else but a sea voyage can bring?

In these days of censorships and meddling by officials with the affairs of individuals, there is room for a Suppressor of Dangerous Inventions. The Comptroller-General of Patents may, indeed, refuse to grant a patent for an invention of which the use would, in his opinion, be contrary to law or morality, but that hardly meets the present case. While patents for house-breaking tools and lottery machines and the like are thus discouraged, Lieut. Bersier's automatic electric steering compass has been tried in the French squadron for several months, and is honoured by a long description in *The Times*. The invention, though calculated to destroy more lives than the most lethal torpedo, deserves some attention on account of its ingenuity. To avoid the making of contact, which would interfere with the motion of the compass card, sparks from a Ruhmkorf coil are used, and in order that the rolling of the ship may not alter the length of the spark-gap, semicircular plates of metal insulated from each other and from the compass bowl to which they are fixed, receive the sparks from the metal point on the edge of the card. Electro-magnets, batteries, a 150-watt motor, and other apparatus is used, and "can be applied to any existing steering gear." Electrical course-signallers, and course-recorders are not new, and, if applied to a separate compass, may have their uses. We are not aware that the many machines and appliances which are to be found in a modern war vessel are intended to reduce the number of the crew, and we are inclined to think that should the crew become reduced to one man, that man will take the helm. Our feelings towards the French nation are too friendly to allow us to hope that this automatic electrical compass will come into extensive use in the French Navy.

The Paper by Dr. Koepsel, of which we give an abstract in our present issue, is one of some practical interest, especially in view of the discussions which have lately taken place on the subject of the testing of iron in workshops. We have frequently called attention in these columns to the danger which underlies most of the methods at present in use, namely, the uncertainty of the effect of joints, and our readers will notice the confirmation of these views given by Dr. Koepsel in the early part of his Paper. We have, therefore, little doubt that he is right when he says that if there must be a joint, it is as well to make so large a gap in the circuit that its effect swamps that of small differences in the contacts made by the test bar. If, as appears to be the case, it is found that the labour of winding complete rings and the trouble of ballistic measurements are sufficient to make the method impracticable, we think that Dr. Koepsel's apparatus is one deserving of consideration. The observations are of the very simplest. The men who, according to the speakers at the Institution of Electrical Engineers, are often incapable of reading a galvanometer deflection, are surely capable of reading the position of a needle on a dial.

Whether the instrument is sufficiently accurate for all purposes is not clear, as the size of the curves is such that the reader is unable to judge by what percentage the ballistic and deduced curves differ, and we must therefore take it on faith that they do not differ much. But it must be noted in this connection, that a small error in the value of **B** may produce a large variation in the area of the curve, a point which is important in connection with transformers. Other questions arise which can only be settled by practical work with the apparatus. For instance, would it not simplify matters to make it a torsional zero-reading instrument, and thus do away with the compensation which would be necessary for the magnetising effect of the swinging coil itself? The author does not mention this, and it is quite possibly so small that it can safely be neglected.

It looks as if some alternator builders were really thinking seriously of following Mr. Blakesley's historic suggestion, that they should build their machines to give "true sine curves," in order that the theory of the machines might correspond with his geometrical methods. The practice has recently become extremely popular in America, where a considerable number of manufacturers are advertising the possession of a "true sine curve" as a valuable feature of their alternators. The grounds upon which such claims are based do not always strike one as being adequate, and one may be forgiven for harbouring a little doubt about the purity and excellence of the "sine" which may be tapped at the terminals. Whether the alternator builders are striving to impart some fresh objective value to their machines, or whether they are graciously trying to get their machines into step with the effusions of the mathematicians, or whether those same effusions have acted injuriously on their otherwise practical brains, we are unable to say. Probably an alternator with a true sine curve, even though it may disdain to run in parallel with a machine having a more bactrian characteristic, is little or no better intrinsically, from a commercial point of view, than the less highly-bred article. But the former has the dignity of hob-nobbing with the text-book mathematicians, while the latter knows only the greaser and the switchboard attendant. Some day a steam engine builder may advertise a steam engine guaranteed to give "true hyperbolic expansion" and a text-book indicator diagram. Then the mathematicians will swarm around that engine, and with tears of joy they will get it coupled to the alternator with the "true sine curve."

Mr. S. A. Varley.—The Government have granted a pension of £50 per annum to Mr. S. A. Varley.

Personal.—The degree of LL.D. has recently been conferred upon Mr. Nikola Tesla by the Columbia College, U.S.A.

Tramways Institute of Great Britain and Ireland.—At a special general meeting of this Institute held at the Holborn Restaurant yesterday, a Paper on "Electric Traction" was read by Mr. A. Dickenson.

The Indian Telegraph Department.—The Telegraph Department continues to open new offices, in spite of the scarcity of money, says the *Indian Engineer*. No fewer than 76 new combined offices have opened since April 1st.

Telegraphic Communication in Japan.—Included in the Japanese Budget for the financial year 1894-95 is an item of £15,570 to provide for the establishment of a submarine cable between Saga-Leki, Okmaiva, and Oki.

German Professorial Appointments.—Prof. Ludwig Boltzmann, of Munich, has been offered the chair of physics at the

Digitized by Google

Vienna University, rendered vacant by the death of Prof. Stefan. Prof. Kaiser, of Hanover, is to be the successor of Hertz at Bonn.

Royal Institution.—At the last general monthly meeting of the Royal Institution the special thanks of the members were returned for the following donation to the fund for the promotion of experimental research at low temperatures:—Sir Douglas Dalton, £25.

Waterloo and City Railway.—A coffer dam is now in process of construction on the Surrey side of the river just above Blackfriars Bridge to enable a shaft to be sunk for the purpose of facilitating tunnelling under the Thames in connection with the Waterloo and City Railway.

Cable Interruptions and Repairs:—

	Date of Interruption.	Date of Repair.
Tarifa-Tangier	June 12, 1894	June 24, 1894.
Bissao-Bolama	Nov. 24, 1893	—
Sierra Leone-Accra	July 2, 1894	—

The Commercial Cable Company's New Cable.—Messrs. Siemens Brothers have telegraphed that the steamer "Faraday" completed the laying of the Commercial Cable Company's third Atlantic cable on Monday. The insulation was perfect. During the laying of the cable no hitch of any kind occurred, but since the last report operations were much impeded by dense fogs.

Epping Forest Railway.—In the House of Commons on Tuesday, on the motion of Sir J. Kennaway, the London, Walthamstow, and Epping Forest Railway Bill was ordered to be recommitted to the original Committee, the Committee having leave to sit and proceed upon Thursday. The original Committee could not, however, be got together yesterday. We understand that the promoters of the Bill and the London County Council have come to terms as to the running of workmen's trains.

A Telegraphic Celebration.—The 25th anniversary of the establishment of cable telegraphic communication with the Far East will be celebrated by a banquet at the Imperial Institute, on Friday, July 20th, to be attended by gentlemen representing every section of the British Empire. More than 500 guests will be present at the banquet, which is to be followed by a reception and garden *fête*, for which several thousands of invitations will be issued. A very interesting feature of the celebration will be the display of cable telegraph instruments in working communication with the four quarters of the world. The instruments will be used by the Prince of Wales during the evening for the despatch of messages to the Governors of the various British Colonies and Depencies, and for receiving replies thereto.

Proposed Extension of the Faure Patent.—The Electric Construction Company as we announced last week in another column propose to petition the Privy Council to prolong the life of the Faure Patent, No. 129 of 1881 for "Improvements in Galvanic Polarisation Batteries or Magazines of Electricity and the Application of the same and in Apparatus connected therewith," the title and specification of which patent have been altered and amended by disclaimer and memorandum of alteration filed January 10, 1882, and which title so amended is "Improvements in Galvanic Polarisation Batteries or Magazines of Electricity." Notice is given that on August 13th application will be made for a time to be fixed for hearing the matter, and any person desirous of being heard in opposition to the petition must enter a caveat to that effect in the Privy Council office on or before that date.

Northern Society of Electrical Engineers.—Arrangements have now been completed for an excursion to the Antwerp Exhibition. A special saloon carriage will be attached to the train leaving the London Road Station, M. S. and L. Manchester, at 3 p.m., on Friday, 20th July, arriving at Harwich at 9:20 p.m. The party will embark on the steamer which leaves Harwich (Parkeston Quay), at 10:15 p.m. and arrives in Antwerp at 10 a.m. Saturday. The party will return from Antwerp at 6:45 p.m., on Monday, 23rd July, arriving in Manchester at 3 p.m. the following day. Those members who do not find it convenient to travel from Manchester can join the party at Harwich. Friends of members, wishing to accompany the party, may be introduced according to No. XXVI. of the "Rules and Regulations." Messrs. Thomas Cook and Sons are arranging for hotel accommodation.

The Electric Light and Naval Photography.—An interesting experiment has been tried at Devonport, which had for its object the testing of the adaptability of the electric light to an instantaneous system of naval photography. The electric light was worked from the dynamo on the port flagship "Devastation," from which a cable was laid to Cremyll. The rays lit up the Hamoaze and its surroundings with picturesque effect, and demonstrated the uses to which electricity can be applied in naval and military as well as in other walks of life. More recently the operations extended over a wider area. The current on this occasion was supplied from dynamos on the "Scourge," moored in Barnpool, to Garden Battery, and the illuminant was, the *Naval and Military Record* says, so penetrating that photographs were procured of two torpedo-boats belonging to the "Defiance," which had been despatched outside the breakwater.

A Large American Alternator.—There is now in process of construction at the Schenectady works of the General Electric Company a large alternator, which is to be completed by August 15th for the Edison Illuminating Company of St. Louis. The alternator is to be of 16,000 lights capacity, and will be coupled direct to a Corliss-Hamilton engine of 2,000 H.P., and will be one of the largest ever constructed in America. It is the first of a series to be built by the General Electric Company for the St. Louis Lighting Company. As may be judged by the output of the machine, its dimensions and weight are very great, the armature being 16ft. in diameter, the diameter of its shaft 20in. and the weight of the armature without its shaft 75,000lb. When completed, the armature core and coils will be tested by an alternating current of 5,000 volts. This alternator, which will be run at a speed of 90 revolutions a minute, making 7,200 alternations and giving an output at full load of 800 kilowatts with an electromotive force of 12,000 volts, will have 80 field poles of laminated iron and an ironclad armature. The curve of the electromotive force, it is claimed by the builders, will be a perfect sine curve, and a type of construction will be followed which will allow the fields to slide upon rails parallel to the axis of the armature, which will make it possible for ready access to be had for making repairs.

The New Wood Arc Lighter.—The Fort Wayne Electric Company, which had made a name and a business for itself by the manufacture of the Wood closed-coil arc-lighter with a brush-shifting regulator, was one of the many electrical manufacturing concerns captured by the General Electric Company in its recent raid upon the electrical industry of the United States. A few weeks ago the captured Company suddenly severed its connection with the General Electric Company and celebrated its freedom by giving birth to "the largest self-contained arc machine ever built." On a recent test it ran 153 9·6-ampere arcs on a 38-mile circuit for a period of 18 hours. The following data regarding the machine will prove of interest: E.M.F. at terminals, 7,050; revolutions per minute, 500; weight of armature complete, 2,288lb.; weight of dynamo, 14,600.b.; weight of dynamo with sub-base, 15,800lb.; temperature of field magnets after 10 hours' run, 68°C.; temperature of armature core after 10 hours' run, 95°C.; temperature of wire, 60°C.; temperature of room, 27°C.; In the new machine the field magnet frame has been placed in an upright position. The cores upon which the field coils are wound are massive wrought-iron forgings, joined by a heavy cast-iron yoke at the top and provided with cast-iron pole pieces. But perhaps the most novel feature is the fact that the Wood machine was coupled direct to a Willans high-speed engine. This combination was got up to meet the specifications of the Detroit municipal electric light plant.

What is Entropy?—It is not surprising, writes Prof. Lodge in the *Engineer*, that some doubt has been expressed as to the usefulness of the conception of entropy to engineers. I myself was somewhat doubtful about it, thinking it possible that the essential facts represented by its laws might be better grasped

Digitized by Google

and dealt with in other and more indirect fashion. But I find that the leaders in engineering science are coming to the conclusion that the ideas connected with the term are essential, and that the term itself is decidedly useful as briefly summarising those ideas. No fresh idea can be practically useful until we have grown accustomed to it. The term temperature by this time feels all right, so do the terms heat and pressure and volume; but the term entropy has at present an unusual sound, and still feels like something abstruse and troublesome. If its employment were to have the effect of really complicating the explanation of things, then its introduction should be resisted forcibly; but if things are themselves complicated, and the entropy, or any other method, introduces a reasonable simplification and comprehensiveness into their treatment, then its introduction is justified. . . . A more or less helpful analogy is the following, based on the fact that entropy is a thing which falls in temperature down an adiabatic, without altering in quantity, so that it is in that respect like the water of a waterfall. It is one of the factors of energy but not the whole; the other factor is temperature above average surroundings—or height above average level in the case of the water.

Municipal Electric Lighting at Manchester.—The report of the Electric Light Department of the Manchester Corporation for the year ended March 31, 1894, was submitted to the Council at its meeting on Wednesday. The supply of current was commenced on July 31, 1893. The number of consumers at the close of the year was 412, and the number of incandescent lamps in use was 18,478, arc lamps 250, and 11 motors, representing 16-H.P. The total quantity of current supplied and charged for was 439,379 units, and the amount of revenue from both methods of charge, including fixed charge per lamp and rate per units consumed, was £1,067, which works out to about 5½d. per unit. The amount for which borrowing powers have been obtained is £150,000, and of this sum £127,830 has been borrowed. The amount of capital expenditure to March 31, 1894, was £127,374. The total amount of revenue from sales of current and rental of meters was £10,198. The cost of generation, distribution, and management was £5,509, to which amount must be added for interest from the commencement of the undertaking £3,461. 6s. 7d.; bankers' commission, £60; and sinking fund, £1,376; leaving a debit balance of £209 to be carried forward to next year's account. The generating plant in operation was estimated to supply an average of about 20,000 16-c.p. lamps, and to be quite equal to any demand which would be likely to be made upon it for two years or more. So numerous, however, have been the applications that the plant is already loaded to its full capacity, and it was found that without extension there would be difficulty in fully supplying the demand for next winter. Under these circumstances it has been decided to extend the plant by one Lancashire boiler, two 360-H.P. vertical compound condensing engines, and two dynamos. These works are now in progress, and will be available for next winter. The applications for a supply of current outside the present area are so numerous that the Committee have decided to make inquiry, and to report to the Council as to the desirability of laying mains in certain leading thoroughfares, and of providing the additional plant and machinery required to generate the current, for which there is every probability of a great demand.

Phosphoresence at Low Temperatures.—The production of liquid oxygen in considerable quantities has afforded a convenient means of investigating the behaviour of substances exposed to light at a temperature of 180deg. below zero, and at a meeting of the Chemical Society held on Thursday week, at the Royal Institution, Prof. Dewar gave an account of the researches which he has lately been carrying out in this direction. Finding that at low temperatures chemical action is almost, if not quite, in abeyance, Prof. Dewar was led to try whether photographic action also ceases. He found that it does not, though it is diminished by 80 per cent. or more. While investigating this, he noticed that the apparatus with which he was working was phosphorescing brightly, and he was thus induced to study phosphorescence itself at low temperatures. Beginning with gelatine and celluloid—substances which he was using in his photographic experiments—he found them to be very luminous when cooled to 180deg., and exposed for a second to the beam of a strong electric light. In the same way phosphorescence was produced in numerous other organic substances, such as ivory, bone, india-rubber, egg shell, feathers, cotton wool, linen, leather, blossoms of flowers, &c. One of the most beautiful phosphorescing bodies was the complex salt, the platino-cyanide of ammonium, which shone with a splendid green light. White of egg was brighter than the yolk, while albumen frozen on the outside of a tube and exposed to light coming through a quartz lens, so that there was no glass to obstruct the ultra-violet rays, phosphoresced with a bright and blue light. From these and other experiments Prof. Dewar is led to the provisional generalisation that the more complex a body is in structure, the more likely it is to phosphoresce, perhaps because, in some way, its structure enables it to take up the light-vibrations with the more facility. Pure water is weakly phosphorescent; but if it is very slightly impure it becomes strongly so. A perfectly clean plate of metal does not phosphoresce; but the merest trace of grease—such as is left by a touch of the hand—will make it brightly luminous. The capability of oxygen for phosphorescing is another curious fact. In the gaseous state it can be made to glow if exposed to an electric spark while rushing into a large vacuum tube. Here, strange to say, the presence of a trace of organic matter destroys the effect. Prof. Dewar stated that a drop or two of ether or of scent in the room would make the experiment impossible for hours.

The Davy-Faraday Research Laboratory.—Mr. Ludwig Mond, F.R.S., has made a proposal to the Managers of the Royal Institution to convey to the members of that Institution the freehold of No. 20, Albemarle-street, to be held by them for the purpose of a laboratory to be named "The Davy-Faraday Research Laboratory of the Royal Institution," and for the purpose of providing increased accommodation for the Institution. The Managers, at their meeting on Monday, most cordially and gratefully accepted the munificent gift made in the communication from Mr. Mond, of which the following is an extract:—

"In the year 1843 a proposal was made to establish at the Royal Institution a School of Practical Chemistry, which was not only to give practical and systematic instruction to students, but was also to provide a place where original researches could be conducted by individuals skilled in manipulation, and where the professors could work out their problems by the aid of many qualified hands. I have felt that the need for such a laboratory has become greater and greater since the work of the scientific investigator has become more and more subtle and exact, and, in consequence, requires instruments of precision and a variety of facilities which a private laboratory can only very rarely command; and surely this need exists nowhere to a greater extent than in England, and nowhere can such a laboratory be expected to bear more abundant fruit than in this country, which possesses such an unrivalled record of great scientific researches, which have emanated from private laboratories not connected with teaching institutions, and amongst which the laboratory of the Royal Institution stands foremost, and has kept up its reputation for nearly a hundred years. It has been my desire for many years to found a public laboratory which is to give to the devotees of pure science, anxious and willing to follow in the footsteps of the illustrious men who have built up the proud edifice of modern science, the facilities necessary for research in chemistry, and more particularly in that branch of the science called physical chemistry. As only want of space prevented the Royal Institution undertaking this task 50 years ago, I took the opportunity which offered itself last year of acquiring the premises, No. 20, Albemarle-street, adjoining the Institution. Being convinced that the managers of the Royal Institution will give all the encouragement and aid in their power in the foundation and working of such a research laboratory, I hereby offer to convey to the Royal Institution the freehold of No. 20, Albermarle-street, and also the lease I hold from the Institution of premises contiguous thereto, to be held by them for the purpose of a laboratory, to be named 'The Davy-Faraday Research Laboratory of the Royal Institution,' and also for the purpose of providing increased accommodation for the general purposes of the Royal Institution, as far as the available space will allow, after providing for the requirements of the research laboratory. I also offer to make, at my own expense, all structural alterations necessary to fit the premises for these purposes, and to equip the Davy-Faraday Research Laboratory with the necessary apparatus, appliances, &c., and to make such further adequate provision as will hold the Royal Institution free from all expense in connection with the premises and the working of the said laboratory. . . . I am aware that my offer will not provide for the third object of the scheme of 1843, viz., to enable the professors to work out their problems by the aid of many qualified hands; but I trust that if the laboratory which I offer to found proves successful, others will come forward who will supply the means for attaining this end, by the foundation of scholarships and bursaries to qualified persons willing to devote themselves to scientific work and not in a position to do so without assistance."

ON IMPULSIVE CURRENT-RUSHES IN INDUCTIVE CIRCUITS.

BY ALFRED HAY, B.SC. (EDIN.)

(Continued from page 230.)

Experiments on Current-Rushes in Circuits of Constant Permeability.

§ 7. The coil used in these experiments had a self-induction of 0·0076 henry, and a resistance of 1·06 ohm at the working temperature. The non-inductive resistance (which was made of platinoid) connected in series with the coil amounted to 0·092 ohm, thus bringing up the total resistance to 1·152 ohm. The periodicity was 125 ∿ per second. Hence, referring to equation (3) of § 4, we have $r = 1·152$; $L = 0·0076$; $p = 2\pi \times 125 = 785$; $\tan\theta = 5·18$, which gives $\theta = 79°$ approximately, and $\sin\theta = 0·98$. We shall suppose that the E.M.F. applied to the circuit is a simple sine function whose maximum value is

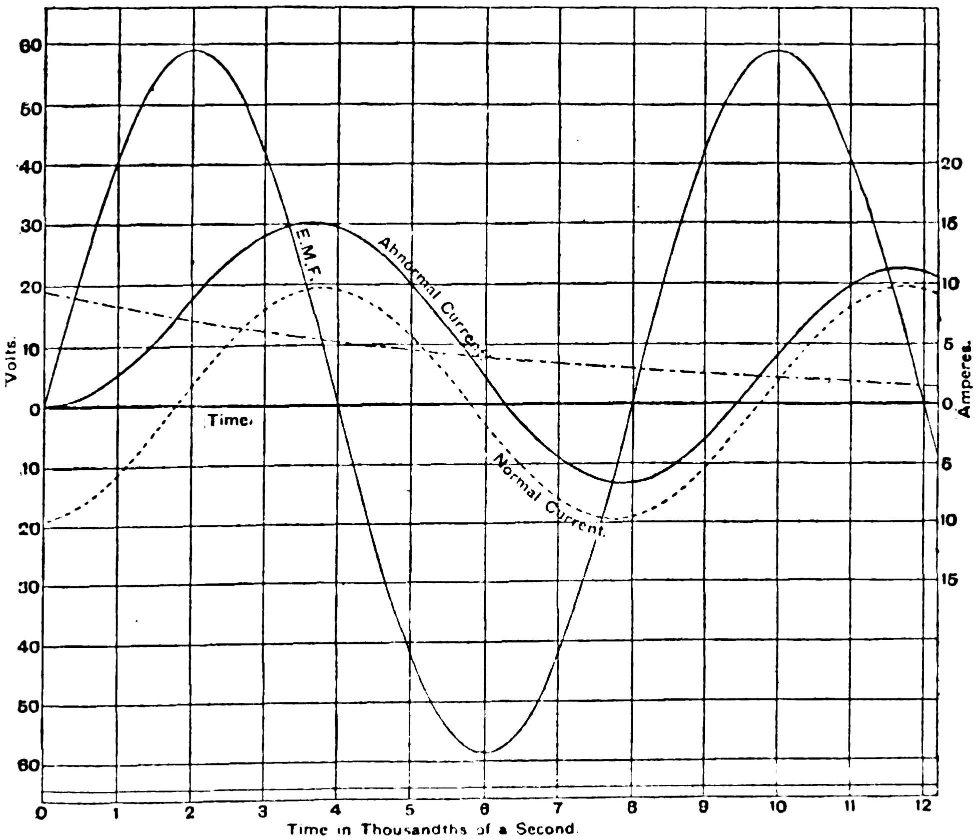

FIG. 2.—Theoretical Curves.

59 (it will be explained in § 8 below why this particular value is chosen). Substituting the values for $E\ \sqrt{r^2+p^2L^2}$, $\frac{r}{L}$ and $\sin\theta$ in equation (3), we find

$$i = 9·7\{\sin(pt - \theta) + 0·98\, e^{-152t}\},$$
$$\text{or} \quad i = 9·7 \sin(pt - \theta) + 9·5\, e^{-152t}. \quad . \quad . \quad . \quad (4).$$

We can now plot the curves of E.M.F. and current on squared paper. The most convenient way of doing this is to assign a number of values to pt in degree measure, find the corresponding sines, and multiply each of these by 59. This will give us the E.M.F. curve. In precisely the same way we may plot the curve of the normal current, given by the first term of the right-hand member of (4), remembering that this curve is displaced relatively to the other by 79°, or 0·22 of the complete period. Finally, we plot the second term of the right-hand member of (4) by assigning to t a set of values which are multiples of some fraction of the complete period. Thus, if we advance by thousandths of a second, or eighths of a complete period, we obtain the following set of values:—

t =	·001	·002	·003	·004	·005	·006
$9·5\,e^{-152t}$ =	·82	·70	·60	·52	·445	·383
t =	·007	·008	·009	·010	·011	·012
$9·5\,e^{-152t}$ =	·327	·282	·243	·209	·18	·15

The abnormal wave of current is obtained by adding corresponding ordinates of the last two curves.

All these curves are shown in Fig. 2, with their corresponding scales. The sine curve of greatest amplitude is the E.M.F. curve; the dotted sine curve is the curve of normal current, after everything has settled down into a steady periodic state. The chain dotted curve is the exponential function which distorts the current waves, the result of the distortion being shown by the thick-line curve, which, it will be noted, is not symmetrical with respect to the axis of time. The greatest ordinate of the abnormal current-wave during the first half period is about 15·2, so that the current-rush (see § 3) is $\frac{15·2}{9·7} = 1·57$.

§ 8. We shall now compare these theoretical curves with curves obtained experimentally for the same coil. These are given in Fig. 3, the points determined by experiment being indicated by small circles. The E.M.F. curve, it will be noted, differs from the corresponding curve of Fig. 2 in being somewhat more sharply peaked; on the whole, however, the deviation from the simple sine form is but slight. The fundamental harmonic of the curve has an amplitude of about 59; this is the reason why in plotting the theoretical curve we assumed an amplitude of 59. The normal current curves are almost identical in the two cases, the higher harmonics producing but little distortion in the experimental curve. There is some difference between the initial current waves; the first, fourth, and fifth quarter-waves are almost coincident in the two cases, but the second and third quarter-waves, although similar in form, appear to be somewhat displaced relatively to each other. The current-rush in the first half-wave of the experimental curve is $\frac{15}{9·7} = 1·55$, which differs but little from the theoretical value (§ 7).

§ 9. The general agreement between the theoretical and experimental results will at once be apparent; a single glance at Figs. 2 and 3 would, in fact, be sufficient to establish the soundness of the theoretical predictions regarding the current-rush. In § 4 it was pointed out that the greatest rush occurs when the circuit is closed at the instant corresponding to the zero value of the E.M.F. In order to test this point, experi-

Digitized by Google

ments were made to determine how the value of the current-rush is affected by varying the phase of the E.M.F. at which the current is switched on, and it was in all cases found that a displacement from the zero value of the E.M.F. reduced the rush. In this, then, also, theory and experiment are in complete accordance.

Since we are dealing with a circuit of constant permeability, it follows that the current curves in Fig. 3 will also be, to some different scale, curves of magnetic induction. We may speak of a "rush" in the magnetic induction just as we speak of a "rush" of current. There is thus a "rush" of magnetic induction accompanying the current-rush, and it follows (§ 5) that this rush must always be less than 2.

§ 10. Having thus shown, both theoretically and experimentally, that current-rushes occur in circuits of constant permeability, we may now briefly sum up our knowledge regarding such rushes as follows :—

(1.) The phenomenon of a "current-rush" (accompanied by a corresponding "rush" of magnetic induction) consists in the appearance, at the instant of closing the circuit, of certain abnormal waves, which *gradually* become modified so as to assume the normal form.

(2.) The distortion of the initial waves consists in an enlargement of one set of half-waves, accompanied by a reduction of the other set. As time goes on, the abnormally large half-waves diminish in size, and the abnormally small ones increase, until a state of equality is reached, which is the normal state.

(3.) The current-rush is a function of the resistance and inductance of the circuit; it increases with the latter, and diminishes with the former. In no case, however, can it attain the value 2.

(4.) The change from the abnormal to the normal state takes place comparatively rapidly at first, then more and more slowly. In all cases where there is a considerable rush, an interval of time corresponding to *several periods* must elapse before an even *approximately* normal state can be reached.

(5.) The damping of the abnormal waves is due entirely to the resistance of the circuit. This will be evident from equation (3) in § 4. It is interesting to consider what *would* happen (and what, of course, never *does* happen) if the circuit could be entirely deprived of resistance. Putting $r = 0$ in equation (3), we get

$$i = \frac{E}{pL}(\cos pt + 1), \quad \ldots \ldots \quad (5)$$

which shows :—(*a*) That the waves would preserve their initial type without undergoing any modification; (*b*) That they would lie entirely above the time-axis; in other words, that a simple harmonic E.M.F. would produce, not an alternating, but a *uni-directional* fluctuating current, and hence (*c*) that the magnetic induction would always be of the same sign. Although no circuit in practice can be made to produce these rather extraordinary effects, yet, by increasing the time-constant of a circuit as much as possible, we can get a current-rush which does not fall far short of two, and abnormal waves which will (owing to the small amount of damping) preserve their type over a considerable number of periods.

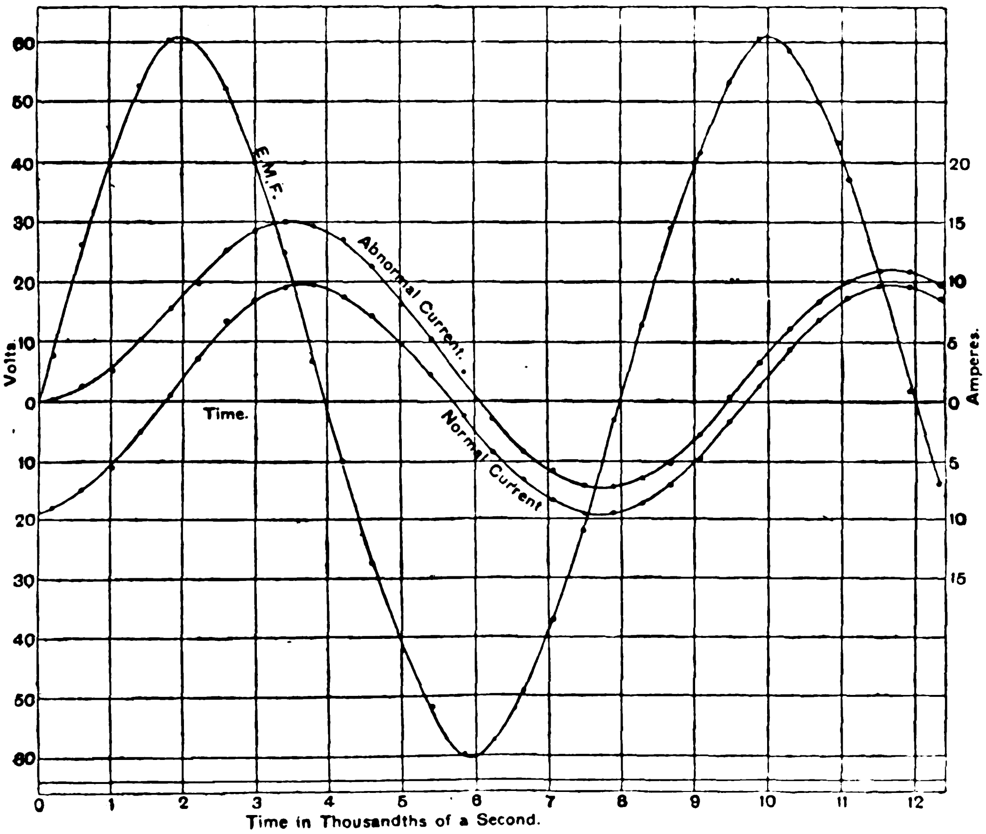

Fig. 3.—Experimental Curves.

Erratum.—On page 230, line 15 from top, omit the words "and to reduce the ordinates of the positive half-waves."

(To be continued.)

ELECTRIC MOTIVE POWER.*

BY ALBION T. SNELL.

(*Continued from page 659, Vol. XXXII.*)

Electric Transmission of Power in Mining Operations.

Perhaps the most obvious field for the utilisation of electricity in power work is to be found in mining. At all events, the first practical plants were applied for mining purposes, and by far the greater number of electric motors running in Great Britain to-day are used in this connection. The superiority of electricity as compared with compressed air or hydraulic power for driving dip pumps and other underground machinery was recognised as soon as the electric motor was discovered. But it was not until about 1885 that the new plant was well enough engineered to be cheap and reliable. The first application of

* All rights of reproduction reserved.

Digitized by Google

sufficient magnitude to demonstrate indisputably the possibilities of the electric motor was made at Messrs. Locke and Company's, St. John's Colliery, Normanton, by the General Electric Power and Traction Company (Immisch and Co.), to the designs of the author. The motor was of about 60 brake horse power, and worked a set of ram pumps raising 120 gallons of water per minute through a vertical head of nearly 900 feet. It was an assured success from the start, and although modifications and improvements have been since introduced in many of the details, the general principles still obtain as standards for continuous current mining work. The application of polyphase currents has opened up fresh possibilities and largely extended the scope of electric power work by obviating the need for commutators and brushes, and therefore removing the chief objection to the use of motors in collieries. The author confidently regards polyphase motors as essentially the machines of the future for mining work.

There is a wide difference between collieries and metalliferous mines in the character of the work; and, indeed, the local conditions of different mines vary so largely as to require special treatment in almost every case. But the main difficulties peculiar to mining work, *i.e.*, which do not usually obtain with surface plants, may be classified under three heads:

(*a*) "Falls" from roofs and sides, and "creeping" of the floors.

(*b*) Water, either continuous or intermittent.

(*c*) Explosive gases.

These may occur singly or conjointly, and evidently require properly selected plant and careful disposition of mains, junction boxes, switches, cut-outs and machines. What is successful at one pit, or part of a pit, is not necessarily so at other places; and hence various methods are employed—some good and some indifferent. Only an engineer experienced in this class of work is able to specify with fair probability of success the best kind of material, and most suitable method of erecting plant for each case. Much defective work has been done from want of practical acquaintance with collieries and mines, although the plant supplied has been usually good of its kind. The bugbear of competition—the lowest tender—has also much to answer for here as well as in other departments of electrical engineering; and the practice of asking contractors to tender to their own specification instead of to that of an independent consultant has largely contributed to the breakdowns which are far more frequent than need be. The absurdity of such a course is rendered the more apparent when it is considered that however up-to-date the mining engineer may be, he cannot possibly have such a close acquaintance with the quality and classes of electric cables, different *points* in dynamos and motors, and the various details of an electric plant as the expert who gives his entire time to such work. And, moreover, the expert is not hampered by patents or special types of machines, etc., as a contractor is very likely to be, especially if he be a manufacturer.

It is proposed to consider here some of the chief difficulties peculiar to mining work, and to examine the methods most in vogue to meet them, and also to suggest, as far as possible, the best plant and disposition of same to do different work under various conditions.

It is convenient to treat this part of the subject under the following divisions:—

1. Engine House and Equipment.
2. Conductors, Shaft, and Underground Cables, Junction Boxes, Switches and Fuses.
3. Motors and driven machines.

These will be considered in separate sections.

Engine-House and Equipment.

The engine-house will generally be upon the "surface," although in some cases where a steam-engine is already at work near the pit bottom it may be necessary to erect a dynamo below ground. Electric plant frequently plays so small a part in the main machinery of a colliery that it is not permissible to provide a separate house for the dynamo. In such cases the winding-engine house or the fan-engine house will be probably selected. If the fan-engine has a margin of power, and is kept running at a constant speed, it may be possible to couple the dynamo to it through a fast and loose pulley. But this is not a common occurrence, nor is it always advisable. The fan forms a steady continuous load, and its engine should be carefully proportioned, both as regards size and speed, to give the most efficient running. And further, since the safe working of a colliery depends to a very large extent upon the ventilation, many mine managers very properly refuse to allow fan-engines to be put to any other work than that of driving the fan.

It may be assumed, then, that the dynamo (or dynamos) will be driven by an independent engine. In the early days of electric work in mines it was frequently necessary to use any odd engine that happened to be available at the time, and hence some very curious combinations. The author has seen a modern efficient dynamo coupled by belting to a large slow-speed engine of antiquated type, rendered still more inefficient by being supplied with wet steam at less than 40lb. pressure, so that the high efficiency of the dynamo was practically annulled.

Managers, however, are beginning to recognise the saving in coal and steam made by using high-pressure boilers and quick-running engines, and the electrical engineer has now little difficulty in arranging for suitable steam plant. Having regard to the fact that the fuel burnt at collieries is usually the most unsaleable there, and frequently almost dust, mechanical stokers are of special use. Vicars, Proctors, or any of the well-known types, answer the purpose admirably, and will be found to effect economy in labour. The type of boilers will depend upon the class of water and local circumstances. Generally, however, Lancashire boilers, with cross tubes, give the best all-round results, and have the advantage of being easily set and repaired by ordinary labour. The working pressure may vary from 80lb. to 120lb. per square inch. Whereas multitubular boilers, although admirable for raising steam at short notice, are comparatively difficult to clean out, and require much more careful attention and skilled labour to effect repairs. The same applies to water tube boilers in connection with this class of work.

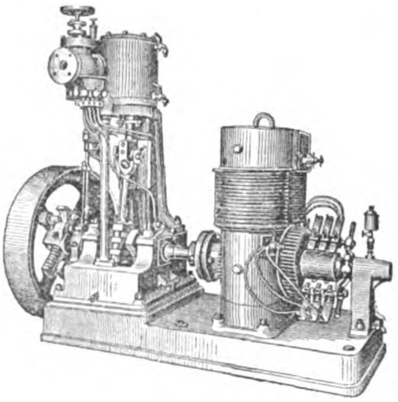

Fig. 100.—Steam Dynamo-Open-Type Engine

In most cases where the engineer has a free hand, and the pressure does not exceed say 500 volts, he will advise steam dynamos—*i.e.*, engine and dynamo directly coupled. See Fig. 100. This arrangement gives a positive drive, reduces the space occupied to the smallest dimensions, effects considerable saving in first cost, and gives increased facility for repairs; while a stand-by set can be compactly placed ready for instant use at a moderate increase in the cost of the running plant. Granting the use of a high-speed engine, the question of open or closed type arises. There are various arguments in favour of each. The open type (see Fig. 100) has the advantage that all the rods and bearings are in full view, and can be inspected while the engine is running, and also it is readily got at to make repairs. But it is likely to be affected by dust, and is to some extent liable to accidental damage from external causes.

The closed type (see Fig. 101), on the contrary, is completely protected from dust and chance external damage, and the crank shaft splashes into a lubricant in the crank chamber, thus

Digitized by Google

ensuring lubrication so long as the oil is maintained at the proper level. The chief objection is that repairs, however trifling, necessarily take a long time to execute, for the casing has to be first removed, and then the rods, &c. cooled before anything can be touched. And if the crank chamber be allowed to run dry, the big-end brasses may be cut to pieces before the fact is noticed. This should not be a common mishap, however. Messrs. Willans and Robinson supply with their well-known closed-type engines a sight gauge, which shows continuously the height of the lubricant in the chamber. The speed of the engine will be selected with reference to its dimensions and that of the dynamo to which it is to be coupled. The number of revolutions will be large compared with those mining managers are accustomed to, being from about 300 to 500 per minute. The question of single or double-acting engines is a wide one, and both sides are admirably championed. Perhaps both types, if properly made, are equally good.

The type of dynamo will depend very much upon the class of work. The pressure, as already suggested, will not be much higher than about 500 volts. A number of manufacturers build excellent machines, and it is easy to select a suitable dynamo or motor if a fair price be paid.

In plants where the work comprises pumping, hauling, coal-cutting and lighting, the generators should be capable of parallel working, feeding omnibus mains. But if there are only large motors, each coupled to, say, pumps or other independent machines, then it may be advisab'e to run separate

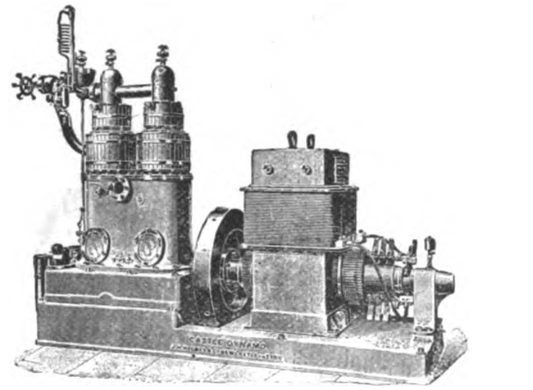

FIG. 101.—Holmes-Willans Steam Dynamo-Closed-Type Engine.

pairs of mains to each motor, and to have a separate generator to each circuit. If the loads permit of one type of motor and one type of generator, a couple of spare machines will be sufficient to cover all. For driving pumps series winding is usually preferable for both generators and receivers if a continuous current system be adopted.

If polyphase currents be used the same suggestions are applicable with suitable reservations. The pressure at the generating station may be restricted to about 500 volts, and then transformers will not be necessary for stationary motors of from 10 b.h.p. and upwards. But in coal-cutters and rock-drillers this pressure is too high for the men to handle the machines with comfort, and it will be advisable to use step-down transformers to reduce it to about 50 volts. At this pressure a "shock" will be impossible and the machines can be safely worked even in the dampest places.

In some cases of long-distance transmission it may be advisable to use a much higher pressure in the "line" between the generating station and the step-down transformers. The question then arises whether the line pressure should be reduced to say 500 volts at the pit bank, supplied at this pressure to large stationary motors, and further reduced for small or portable machines. These are questions, however, which must be decided for each case upon its merit, and a mine manager will do well to take the opinion of an independent expert before signing a contract for plant.

Shaft Conductors.

The classes of conductors suitable for the severe conditions of mining work are not very numerous and differ chiefly in the kind of insulation, and the means employed to protect them from mechanical injury and the effects of water.

Broadly there are two kinds of insulation which have stood the test of time, viz, vulcanised rubber and bituminous compounds. The former class is costly and thus better adapted for the lighter classes of cables, say up to strands of 19/15 S.W.G., which, owing to their position, do not require to be covered with a coating of lead or armoured with steel strip or galvanised iron wire. The latter class is cheaper and hence is more suitable for large trunk mains; but since it rapidly loses its insulating properties if in contact with water, it is necessary to encase the compound with lead which should be armoured to protect it from injury. The best form of bituminous cable is made concentric see Fig. 102. The centre conductor is doubly guarded and even if the metal sheathing be cut through only the outer conductor is earthed, and the cable as a whole is workable until an opportunity occurs for repairing the injury.

The author finds it expedient, even in large plants, to limit the size of each conductor to, say, a cable of 19/14 S.W.G. strands; and, if this be of insufficient cross section for the current, to duplicate the conductors and connect them to omnibus bars. With this provision an accident to one conductor does not cause a complete stoppage, for the damaged cable can be disconnected until the fault be localised and repaired. It is oftentimes a matter of impossibility to make repairs during the drawing of coal, and hence the importance of providing spare

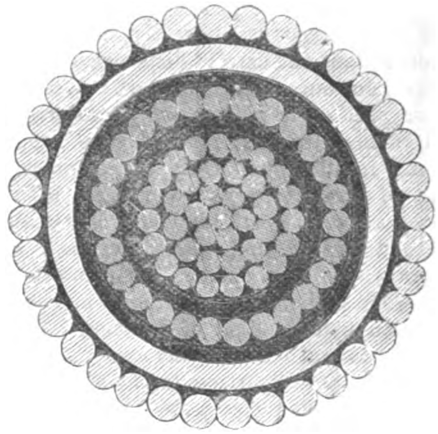

FIG. 102.—Armoured Concentric Cable with Lead-Covered Bituminous Insulation.

conductors. Also the weight of the smaller main, or pair of mains in concentric form, is less and it is more easily handled and fixed in position. And, further, the cost of repairs to the smaller size of cables is generally much less, owing to the greater ease with which the joints can be made.

The methods of running cables down shafts and fixing them in position differ in almost every case. Pit shafts are usually of circular form, sometimes driven through the live rock, sometimes built round with courses of brick or stone laid on cast-iron cribs at intervals, sometimes faced with heavy timber walls, and occasionally lined with cast-iron sections through quicksands or strata heavily charged with water. If wooden "*conductors*" are used to guide the cages, heavy cross bearers of timber are built into the sides of the shaft at intervals to carry them. When iron rope guides are used, the shafts are practically void of timbering.

These different conditions evidently demand different methods of supporting the cables.

In the first place, it is absolutely essential to guard against falling coal and stones either from the cages or from the sides of the pit. The best position for placing the cables will, therefore, be largely determined by the shape of the cage, and whether its sides are covered up so as to restrict the falling of loose pieces of coal to the open ends. Again, stands of iron pipes already placed may limit the space still further. In general it is not advisable to run electric cables near to pipes, because workmen repairing the latter may damage them. Another consideration of importance is whether the up-cast or down-cast pit is the better adapted for the purpose. If the "winding" be done from the down-cast, as is usual, it may be convenient

Digitized by Google

to use the up-cast. But care must be taken that the up-cast air is not laden with any erosive vapour, such as is sometimes the case when the exhaust from an underground engine and the gases from a furnace, burning coal containing a large percentage of sulphur, are turned into the up-cast. The author knows of one case in which a pair of lead-covered cables run in such a pit were corroded through in dozens of places in the course of a few months. In some soils there are found erosive agents that attack iron and rapidly rust it away, and in others a similar action takes place with lead. Generally it has been the author's practice to use the down-cast shaft; but there is no rule, and in all cases it is possible to ensure success by making suitable arrangements.

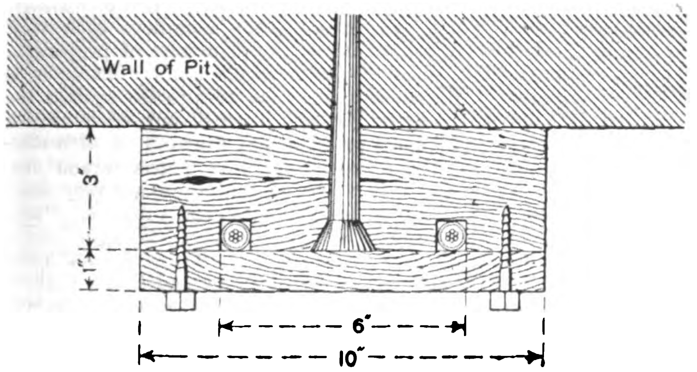

Fig. 103.—Wood Casing for Pit Work.

The plans adopted for supporting cables in shafts differ widely. In all cases, however, where it is desired to give the work a permanent character, the cables must be entirely encased in wood, run in iron pipes, or heavily armoured. These three methods are not always equally applicable from various considerations; and local conditions may make one of them the cheapest or most desirable. If there are a set of say 4in. pipes already erected in a shaft, and it is desired to run a pair of say 19/16 S.W.G. cables down them, and the depth is not great, a pair of vulcanised rubber mains may possibly be suspended in them from earthenware insulators. The weight on the supports will not be great, for the cable will sag from side to side of the pipes, and thus may nearly carry its own weight if sufficient slack be allowed. In running cables down pipes,

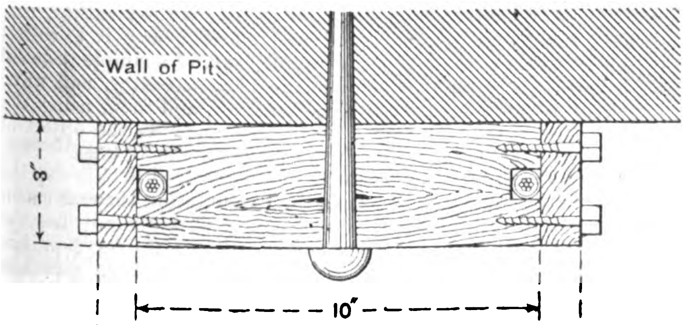

Fig. 104.—Wood Casing for Pit Work.

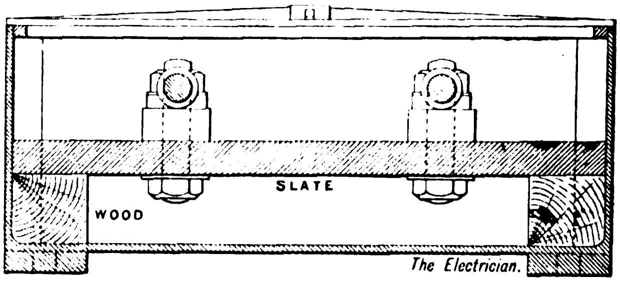
it is advisable to first insert a small flexible iron rope, and use this to haul in the insulated conductor, which should be payed out from the drum, perpendicularly into the centre of the pipes, over a wheel of sufficient radius. This method prevents damage to the covering of the cable. The interior of the pipes should be scoured to clean off sand from the cores, or the insulation will inevitably be abraided during the hauling-in.

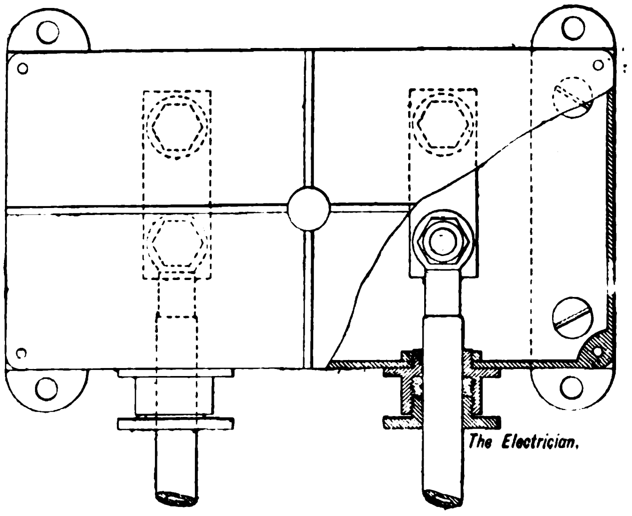
If the pipes be of large diameter, and the depth too great for the mechanical strength of the cable, it is necessary to support it at intervals. This may be done in several ways, but it will be necessary to break the continuity of the iron pipes to insert wedges, clamps, or similar devices.

It may be better then to adopt a wooden casing which will support the cable all along its length. In using wood, however, care must be taken that the section is of sufficient strength, and that the "lengths" are spiked firmly to the pit sides. The grooves may be cut in the face, as shown in Fig. 103; or in the sides of the casing, as in Fig. 104, which illustrates a method used most successfully by the author in a number of mines. The covering boards may be held in position by coach screws. This enables an examination of the cables to be made at any spot—which is oftentimes a convenience. The grooves should be cut an easy fit for the cable, which will then be perfectly supported, and only a light attachment at the top is necessary. It is always advisable, however, to securely loop the top ends around earthenware insulators firmly carried at or near to the surface.

Concentric cables lead-sheathed and armoured are so stiff that they may be clamped directly to the pit sides, and then form a strong compact job. As they are very heavy, there is need for strong brake gear on the surface to pay them out by, as they cannot be fastened in position until the whole length is down the pit. It is advisable with very heavy cables to lash ropes at intervals, and pay them out at the same rate, thus relieving the top end of the cable of part of the weight. This class of cable is steadily finding favour for pit work.



Sectional Elevation. One-third full size.



Plan (part section). One-third full size.

Fig. 105.—Davis's Junction Box, for use in Mines.

On no account should joints be permitted in new shaft cables, although it may be necessary to make repairs in old ones. A cable with continuous insulation is much more likely to stand the wet and exposure of a pit than one with joints made with a dielectric different from the rest of the insulation, and likely enough defective from the beginning. And it should be recollected that jointing is an extremely difficult operation in a shaft, owing to falling water, the cramped position, and the strong draught of air which together render soldering an impossibility in many cases, and often make the insulation uncertain owing to the presence of moisture. Of course it is possible, assuming time be allowed, to provide special apparatus which in the hands of skilled men will enable excellent work to be done; but breakdowns usually occur unexpectedly, and frequently have to be made good by the resident staff with such simple materials and facilities as may be at hand.

In most cases the author prefers to arrange junction boxes at the top and the bottom of shafts, so that the shaft cables can be severally tested independently of the surface and underground work. These boxes must be housed in dry places secure from mechanical injury. To attain this there should be sufficient

Digitized by Google

free length of cable at top and bottom to allow the boxes to be placed well away from the drawing decks and pit bottom. A very effective junction box manufactured by Messrs. J. Davis and Co. is shown in Fig. 105.

(To be continued.)

THE TEACHING OF MECHANICAL DRAWING.*

BY PRINCIPAL S. WELLS.

Few subjects are more widely taught in technical schools and colleges and on the modern side of ordinary schools, than that of geometrical and mechanical drawing. Indeed, the inclusion of that subject in their curriculum is probably the only claim which some schools have to the title of "technical" or "modern" at all. It is certain that there are few subjects of equal importance taught in such widely different ways, and producing results so varied in quality. Its teachers range from the "art master," whose knowledge of machine details is generally limited to the possession of some badly-arranged diagrams, or out-of-date copies, and whose strong points are seen in the amount of shading and colouring which usually characterises drawings produced under his directions; to the mechanic who has an elementary Science and Art certificate in Subject II., and who teaches the subject much as the famous Chinese tailor taught his art—by simply copying. It is curious also to notice what different drawing courses are adopted in our leading university and technical colleges. In more than one the teaching of practical geometry is pooh-poohed as unnecessary, and the student commences his drawing lessons with "tracing," and learns the meaning of "plan," "elevation," and "section" for the first time when he commences the drawing of some machine part from a copy or model. With this method we entirely dissent; we have the fullest sympathy with those professors who object to the Science and Art syllabus, which puzzles students with maze-like problems on intersection of points, lines, and planes, when they might more usefully be learning how to make a readable drawing; but we contend that practical geometry is as natural and necessary a prelude to machine or building drawing as is the alphabet to grammar, or algebra to trigonometry. We hold a very decided opinion, and this we know is largely shared by others, that the Science and Art syllabus for Subject I. is not suited to the requirements of nine-tenths of our technical students who wish to gain an intelligent knowledge of mechanical drawing. It covers far too much ground for one thing, for graphic arithmetic and statics ought not to be included, and richly deserve a separate classification, and it is not sufficiently practical for the plumber, the bricklayer, the mason, or carpenter, who wants a knowledge of drawing to help him with his every-day work. Geometrical exercises on some of Euclid's propositions or theories, the projections of oblique planes, the actual distance between two imaginary points or lines, and similar problems are no doubt intensely interesting to the mathematical and better-educated student, and form capital mental training; but they are beyond the scope of, and of little use to, the ordinary working youth seeking for something useful and practical, and whose instruction in drawing should be "manual" rather than "mental." We fancy these reasons are at the bottom of the difficulty which is found in getting trade students to attend a drawing class; they prefer to obtain their drawing from their own instructor, who is not likely to give them unpractical work; but we cannot say that we think this altogether the best and wisest system, for its tendency is to narrow the drawing to specific objects without due regard to the teaching of really necessary and useful principles. What is wanted is a course of drawing instruction, which, commencing with the division of lines and angles, and simple problems to teach accuracy, shall continue with the construction of scales and regular polygons, problems in lines and circles, continuous curves, construction of ellipses, simple problems on loci, and leading up to plans, elevations, sections, developments, and interpenetrations of the common regular solids and isometric projections. Such a course as this would be of equal service to workers in all the engineering, metal work, and building trades, and we hope the London Technical Education Board will see to it that the course shall find a place in the time-table of our polytechnics and technical institutes. Engineering and metal-plate work students might well extend the course to include further problems on loci, and the construction of cycloidal curves, as applicable to wheel teeth and other examples of actual construction; and in all cases students should be shown how to develop and make paper or card models of the solids they draw, especially with problems on interpenetration. We believe that a course of this character should be a *sine quâ non* for every student whose work requires him to read or make drawings, and upon its completion he would be in an excellent position to come under the instruction of his own trade teacher, and apply his knowledge to the making of working drawings. It is, however, with the method of this continuation or trade drawing that we are most at variance, for how can a student be taught to make a proper drawing by the process of simply copying from a "copy" or a "model." It is positively appalling to watch the progress of this method of teaching. We have seen students make drawings from copies for months together and never know what they have been drawing beyond the merest generalisations; while, as for the "model" system, we have only to remember seeing students commence to draw a plummer-block by putting in the holding-down bolts, or a stop-valve by drawing the hand-wheel, to create its own condemnation. We say most unhesitatingly that the effect of copies or models is that students do not draw different parts in the right order; they do not learn the names and objects of the parts or their proper relation and interdependence, or the form and sizes of such common parts as bolts, nuts, rivets, washers, bosses, &c., and, worst evil of all, they complete each view separately, and thus entirely overlook the principles of projection, without which design, even of the most elementary character, is utterly impossible. We should like also to protest against the idea that drawing cannot be taught in a lecture, but must receive individual tuition. There are principles of drawing as of mathematics and mechanics; there are methods as generally and usefully applicable as to any other science, and there are very many things which can be and should be taught as class subjects. Such, for examples, are the number and position of different views, most suitable scale, whether sections, and, if so, of what parts are required; method of commencing drawing and fixing position of centre lines, order of drawing different parts, usual methods of showing, and sizes of common parts, and how the sizes of other parts depend upon them, dimensioning drawings, and many other matters which students are left more or less to chance to learn if individual instruction is the only method adopted. Nor must we forget to point out a great evil which results from "dimensioned copies," in that the student never learns the sizes of common parts, and how they, and they alone, determine the sizes of other parts, to which they are connected. We have seen "copies" of cylinders in which every trifling detail was dimensioned, even to the thickness of nuts and the diameter of a split pin, and we say that a student has no more right to draw a cylinder unless he has learned such details as these, than he has solve triangles before he has commenced algebra. We have heard somewhere of a student who commenced the drawing of a connecting-rod by putting in one of the lock nuts, and, although we expect the incident has been somewhat exaggerated, we think it is quite the kind of thing that might happen with the "copy" and "model" system. But we do not wish to be mistaken; we believe in models most emphatically, and in, what is better still, actual examples, and we believe every class in mechanical drawing should be well supplied with practical examples of all common parts. Yet we do not think these models should be distributed among the class and the students told to make drawings of whatever falls to their share; we say rather, that the only really really educational and efficient way is to collect the students in a class, take the example, say, of a simple pedestal bearing, describe what views and sections are necessary, and why; show them first how to fix the centre lines, and then, using the blackboard as a drawing-board, teach them how as the object of the pedestal and bolts is simply to support the brasses. Then the brasses should be shown first, *in all views*; and in this way the parts should be taken and drawn in their right order, the reasons for their form and size explained, but not the sizes given. Let the student sketch the blackboard work by all means—for how few students can make decent freehand sketches—and then give him the problem in the form of a question, in which the name and size of all the parts are stated. They can then separate to their drawing-boards, and, by being allowed to consult their sketches and the model but not to measure it, they will not only produce a drawing, but will understand what it all means when it is done. Of course, this is only an illustration of a method which teachers would modify to suit the capacities of a class; but having seen it tested we know it is workable, and that its results are immeasurably superior to those of the other methods to which reference has been made. We are afraid we must acknowledge that students who follow such a course as this might not be as lucrative to the teacher working for grants as methods more commonly adopted, and there is again the temptation to say that South Kensington blocks the way! But this is not altogether true; their "Machine Construction and Drawing" syllabus is not one of their worst, although it is certainly not their best, and it has become all too easy to seek the mote in their eye without regard to the beam in our own. It would be impossible to teach up to their syllabus by any method in 30 lessons of one hour each; what is really wanted is lessons of two to two-and-a-half hours where half-an-hour to an hour is devoted to lectures and the remaining time to work with the drawing-board. This, and nothing less than this, should be the aim of every institute and teacher who wishes to teach mechanical drawing as it should be taught.

PHYSICAL SOCIETY.

At a meeting of this Society held on June 22, 1894, Prof. W. E. AYRTON, F.R.S., Past President, in the chair, Mr. Larmor was elected a member of the Society.

Capt. ABNEY, before exhibiting his

"Photographs of Flames,"

demonstrated that a candle flame contains solid particles by passing a beam of polarised light through it, the track of the beam through the flame being clearly seen in one direction, whilst in a direction at right angles it was practically invisible. The same thing was also shown by passing the light through a turbid liquid. Photographs of Argand and candle-flames, with pencils of sunlight and electric light passing through, were then exhibited, showing similar phenomena. Several series of photographs of flames of candles and various forms of gas-burner taken with diminishing exposures, were then shown, in order to illustrate the different luminosities at different parts of the flame. Those taken with long exposures showed the bright parts nearly equally white, but as the time of exposure diminished only the most luminous portions were recorded on the plate. From the photographs the author concluded that when used with a slit as a photometric standard, the Argand burner was unsuitable, for portions of different luminosity come into view when the slit is approached or receded from. The ordinary fish-tail burner was better in this respect.

Questions were asked and remarks made by Prof. S. P. Thompson, Prof. Perry, and Mr. Trotter, in reply to which Captain ABNEY said drop shutters with slits from 1in. to $\frac{1}{16}$in. wide had been employed, and some of the exposures were only a few thousandths of a second. The displacement caused when the object was not stationary could easily be allowed for when the velocity of the shutter was known.

Prof. O. HENRICI read a paper on

"An Elementary Theory of Planimeters."

Considering the generation of areas by the motion of straight lines, the author defined the sense in which such areas are to be taken. Choosing the positive sense of a line O T of variable length as outwards from the centre O, about which it turns, and the positive direction of rotation as counterclockwise, the following rule for determining the sense of an area was given: Imagine yourself standing at a point P, and looking along the positive sense of O T, whilst it passes over P, then the area near P will be swept out in *a positive sense if* O T *crosses from right to left*, otherwise it will be negative. Applying this rule to closed curves of any shape, it was shown that if T goes once round the boundary, any area outside the curve was necessarily swept over as many times in the negative sense as in the positive sense; therefore these areas cancelled, and also that the sense of any part of an area depends on the sense of its boundary. Passing on to the consideration of areas generated by a line (or rod) of fixed length, which moves anyhow in a plane, and returns to its initial position, Prof. Henrici showed, by taking instantaneous centres, that the same rule regarding the sense of the areas holds, and that the area generated by the rod is equal to the difference between the areas of the two closed curves traced by its ends. In the particular case where one end of the rod moves forwards and backwards along the same path, the area swept out by the rod is equal to that of the closed curve traversed by the other end.

This is the theory of Amsler's planimeter, for the area of the curve whose boundary is traversed by the tracer is the same as that swept out by the rod carrying the tracer when the pole is outside the closed curve. By resolving small motions of the rod in two component parts, a translator parallel to itself, and a rotation about the point in which the plane of the registering wheel cuts the rod, the author showed that the areas swept out by the translations were registered by the wheel, whilst the sum of those generated during the rotations cancel. Cases where the pole is inside the curve were next considered, and the constant then to be added to the wheel reading determined.

Instead of registering the translation by a wheel whose axis is parallel to the rod, a knife-edged wheel which slides and turns freely on an arm perpendicular to the rod would serve the same purpose. This is the principle of Hine and Robertson's planimeter.* In the actual instrument, however, the arm is inclined at about 10deg. to the rod, and is therefore inaccurate. In the "Hatchet"† planimeter a bent rod terminates at one end in a tracing point and at the other in a convex knife edge or "keel" whose plane contains the point. The area of the curve whose boundary is traversed by the point is approximately equal to twice that of the sector included between the initial and final positions of the rod. The approximation results from the fact that the area of the curve traced by the keel is not zero. At the meeting the question of reducing the area of the keel curve was discussed at some length, the author showing that in the case of a curve symmetrical about a line, it was possible to reduce this area practically to zero. Even for unsymmetrical curves one could obtain a symmetrical one of double the area by drawing a line cutting the curve, and supposing the area turned over about this line.

Prof. PERRY inquired if the author's conclusion was that the Hatchet planimeter and the Hine and Robertson instrument were inaccurate? If so, he was at a loss to understand why the latter gave results more nearly correct than Amsler's.

Mr. BLAKESLEY pointed out that if both arms of a jointed planimeter be simultaneously moved over curves, the total reading should give the sum of the two areas traced out, if taken in the proper senses.

Mr. A. P. TROTTER directed attention to an article by the inventor of the "Hatchet," in the current number of *Engineering*.

Dr. MACFARLANE GRAY said he had examined the proof given in *Engineering* and found no error. He then showed how the Amsler planimeter could be explained in a simple geometrical manner by drawing radial lines through the pole and intersecting the curve. Moving the tracer along these radii added nothing to the area; motion along the arcs was the important component.

Mr. O. G. JONES and Prof. THOMPSON also took part in the discussion.

Mr. F. W. HILL made a communication on

"The Hatchet Planimeter."

In this Paper the author takes a point within the area to be measured and divides the area into elementary triangles, with this point as apex. The tracing point of the planimeter is then supposed to start from the apex, and trace out one of the triangles. The inclination between the initial and final positions of the Hatchet is then expressed in terms of the angle at the apex, the radius sector, and the length of the planimeter. By expanding and integrating the expression it is shown that twice the area between the initial and final position of the planimeter, after tracing all the triangles, is represented by an infinite series of terms, the first of which is the area of the curve, the second is proportional to the moment of inertia of the area about the point, the third proportional to its first moment about the same point. The higher terms are usually small enough to be neglected. Starting the tracer at the centroid of the area causes the third term to disappear and the second has its minimum value, so that this is the starting point recommended. The magnitude of the errors caused by neglecting the various terms are discussed in some detail. In the author's opinion the instrument can never be strictly accurate, but usually the errors are within the limits of observation.

Prof. HENRICI did not agree with the statement that the instrument was necessarily inaccurate, and thought geometry might aid analysis to find the proper starting point. For a symmetrical curve he had shown that a point existed, starting from which the area traced by the hatchet-end was zero.

Dr. MACFARLANE GRAY thought Prof. Henrici's latter argument was vitiated by his figure not being correctly drawn; but this Prof. Henrici disputed.

Mr. O. G. JONES said Prof. Henrici's construction was not obvious, for the crisp curves traced by the hatchet-end depended on the starting point.

Mr. YULE suggested that by shortening the planimeter it might be possible to bring the third and second terms of Mr. Hill's formula into greater prominence, and, by going round the curve more than once, determine the first and second moments.

A Paper on

"A New Integrating Apparatus,"

by Mr. A. SHARP, B.Sc., was taken as read. The Paper describes an improved form of harmonic analyser, giving the amplitude and epoch of each constituent term, the mechanism of which is an inversion of that described in a communication made to the Society on April 13th; numerous drawings accompany the Paper, showing the various parts in detail. The mechanism is also shown to be applicable for integraphs, and by suitable modification may be employed for mechanically integrating differential equations of various forms.

A Paper on "Magnetic Shielding by a Hollow Cylinder," by Prof. Perry; and another on "Clark's Cells," by Mr. S. Skinner, were postponed.

Before adjourning, the CHAIRMAN announced that in future the meetings would be held in the rooms of the Chemical Society, Burlington House.

Platinised Glass Resistances.—In a recent discussion at the Société Française de Physique on a method proposed by M. Mergier for measuring the resistance of the human body, M. Ducretet pointed out what a convenient form of high resistance could be obtained by using platinised glass. A sheet of platinised glass 75 mm. by 110 mm. (3in. by 4¼in.), enables one to get a resistance varying from 25 to 100,000 ohms. The best way to mount these sort of resistances is to place them in a closed bottle containing purified petroleum, a layer of mercury at the bottom of the bottle enabling the resistance in circuit to be brought to any desired value.

Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

"THE ELECTRICIAN" *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as an Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of*—

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Price 12s. 6d., post free 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d. post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free. Also in German, 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free, 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 8s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

ELECTRIC MOTIVE POWER. By A. T. SNELL. [*In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. [*In preparation.*

PRACTICAL MAGNETISM. By J. A. KINGDON. [*In preparation.*

In Preparation. Very fully illustrated.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. Being Four Lectures delivered in April-May, 1894, before the Royal Institution, by Prof. J. A. FLEMING, M.A., D.Sc., F.R.S.

CATALOGUING SCIENCE.

The peculiar peril to which modern science is exposed, that of being buried beneath its own accumulations, has long been dimly perceived by the more prescient, and to-day the possibility of such an eventuality is only scouted by a small but vigorous minority, who hold that the whole duty of scientific man is to go about his own business, untroubled by the reflection that the soil which he is tilling with so much labour may have been long ago exhausted by another. Recognition is one thing, counteraction is another. The world of science has for some time past fully recognised the evil, and it is satisfactory to find evidence in the Presidential address to the Chemical Society delivered last May by Prof. ARMSTRONG and in the recently-issued circular of the Royal Society, that the leaders are ready to take the lead in this matter, and are prepared with some not totally inadequate proposals.

Prof. ARMSTRONG, we are glad to note, sees clearly that this "remorseless cataract," as someone has termed it, "which thunders over the remnants of the past, as if it were a fresh impediment to the men of our day in the way of systematic knowledge and consistent powers of thought; as if it were destined one day to overwhelm the great inheritance of mankind. . . . ," is not only such, but may, even if it fail to overwhelm, have nevertheless a decidedly deadening influence; no effort, says Prof. ARMSTRONG, should be spared "to prevent our being split up into factions and becoming narrow-minded specialists." On the other hand, the Royal Society, it would appear, sees its way to a remedy as clearly as Prof. ARMSTRONG sees the necessity for remedial measures; though it may be remarked, in passing, that the compilers of the circular in question are evidently of opinion that a little confession is remarkably good for the soul, since they devote the first half of it to a minute catalogue of the deficiencies of the existing "Catalogue of Scientific Papers." It is limited, we are told, to periodical scientific literature, no account being taken of monographs, such, for instance, as that by Prof. FERRARIS on rotating vectors, which has lately appeared in our columns, or of

Digitized by Google

independent books, such, we will say, as HELMHOLTZ's "Physiological Optics." But even as regards periodical literature, the present catalogue is said to be "confessedly incomplete," Papers which have the misfortune to appear in unimportant or somewhat inaccessible publications being omitted. Finally, the Papers that do appear on the list are arranged solely according to the authors' names. However faulty the Catalogue itself may be, this catalogue of failings is remarkably complete.

The disagreeable duty of making a clean breast of it once performed, the compilers of the circular proceed to make a series of well-considered suggestions. The great development of scientific literature, they urge, requires the compilation of a compendious international catalogue, published at short intervals by a central bureau in an agreed-upon language, and arranged in accordance with common sense; that is to say, the title, not the text, of a Paper settling its place in the ranks. As to the desirability of international co-operation there surely cannot be two opinions; as to its feasibility there surely cannot be any doubt. The undue multiplication of catalogues is not less to be deprecated than the undue multiplication of memoirs to be catalogued. A publication of the nature proposed and for the purpose proposed can only be expected to prove of real service and to remain the sole representative of its kind if it be subsidised, supported, and edited internationally; and that, not by learned professors in their leisure moments, but by the labours of competent and well-paid physicists, chemists, and geologists, devoting their whole time to the task, and reinforced at frequent intervals by vigorous recruits. Index-making and catalogue-compiling may in this year of grace be a work of necessity and an art of the utmost importance, but nothing can dissociate it from the attribute of deadly dulness. Yet nothing is more indispensable in the performance of such functions—that is to say, if the result is to be of genuine value—than a general mental alertness, and a guarding of oneself against the not unnatural supposition that the titles of Papers bear some relation to their contents. No more useless form of catalogue can be conceived than the Universal Index which it is proposed to publish weekly at Leipzig. Editors of technical and scientific periodicals are requested to send their publications to the editor of the Index and thus "secure a permanent advertisement." The specimen copy before us contains nothing more than the lists of contents of a number of journals arranged in the alphabetical order of the places of publication. Articles which are on their way round the world appear in the list of each journal that has copied them.

Whether such a comprehensive compilation as the one outlined by the Royal Society should be purely and simply a *catalogue raisonné*, or should add to its bulk and to its value by containing something in the nature of an abstract of each item catalogued, is apparently a matter upon which the Royal Society is in some doubt. If we consider, however, for a moment the chief use to which a compendium of this kind would in all probability be put, it would seem as if the balance must inevitably turn in favour of greater bulk and greater value. A research likely to involve many months, it may be years, of thought and experiment suggests itself to a physicist or chemist. He may, indeed, possess a tolerably wide acquaintance with previous work in the same field; but no man, no, not even an editor, is omniscient. A necessary and useful preliminary to such a piece of research is, therefore, a glance backward into the past. At present there is not even so much as a reliable well-arranged catalogue to assist that glance, although it is possible that the scientific world may, from the first day of the twentieth century onwards, be so far blessed. But the labour and money required for a mere catalogue would, with modest additions, suffice for compiling under each of the more important entries a twelve-line *aperçu*—we will not call it abstract—adorned if need be with one of those diagrams which tell so much in so little space; each epitome stating, with rigid condensation, the object of the research, the method employed, the result obtained. To place a bald catalogue in the hands of an investigator will be to tantalise and exasperate him. It will not bring him appreciably nearer to getting a sight of Papers he thinks he wants, or enable him to assure himself that similarity of title does not perchance mean similarity of text. As to the language in which this portentous work should be published, it might be fairly argued on the ground of approximate universality that it should be English, whilst the Germans might urge their extraordinary scientific activity and the French might claim that what is the language of diplomacy all the world over might well serve as a medium for conveying scientific information all over the world. There is, it must be admitted, a certain crisp precision about the French language that neither our own rich native tongue nor the cumbersome German one can hope to attain to.

Such is the complaint, and such is the cure proposed; the one is heroic in its dimensions, the other in its laboriousness. But as we live in an age of preventive medicine, would it not be well to attack the evil at its origin? Diffuseness of style, and over-eagerness to publish, must share the blame between them. We print too soon, we print too much, we print too long. A scientific Tacitus is needed to bring conciseness and compression once more into fashion.

REVIEWS.

The Steam-Engine and other Heat Engines. By Prof. J. A. EWING, M.A., B.Sc., F.R.S., M.Inst.C.E. (Cambridge: University Press, 1894.)

The volume before us is a treatise based upon, and constituting an extension and amplification of, the article by the author in the *Encyclopædia Britannica* on the same subject. When, some years ago, Prof. Ewing compiled that encyclopædic article, it seemed to him that the most appropriate mode of treatment consisted in following, though with considerable compression, his course of lectures to students of engineering. The amplification of this article has therefore led most naturally to the publication of a treatise which is in every sense to be regarded as a students' textbook. Prof. Ewing's book must be regarded in this light, as well for its academic style and scope as for its main purpose, the inculcation of the theoretical principles of thermodynamic machinery. It is a book which will take its place beside the student's "Rankine" and "Cotterill," and in many respects it carries on the useful work begun in them. There is progress in theory as well as in practice; and the engineering student requires not only that the underlying principles of his science should from time to time be edited and presented in a more modern dress, but that accurate account should be given to him of progress in machine construction and practice. It is rarely, if ever, that a textbook satisfactorily combines these two duties; nor is it always desirable that it should endeavour to do so. Prof. Ewing's book is an able exposition of the former—the theoretical—side of engineering studies.

To the issue of a new work on the thermodynamics of heat engines it is possible that objections may be raised. It will probably, on the one hand, be urged, as it is so often urged, that thermodynamics have done nothing to forward engineering; and, on the other hand, it may be objected that all these things are written in the works of Clausius and Rankine, of Maxwell and Cotterill, which are in the hands of every engineering student with any true pretensions to the name.

Digitized by Google

Neither of these objections is valid. Even though it were true that the progress of engineering has not been directly aided by theoretical investigations in thermodynamics, it would still be a fact that indirectly a great deal of assistance to practical progress has been rendered by the insight which the study of this science has afforded to engineers. But it is not true; direct aid has over and over again been given. The introduction of the separate condenser, of high pressure steam, of compound and multiple expansion, of high-speed pistons, the revival of super-heating, are instances of progress in steam practice which has been initiated by a true insight into thermodynamic principles; while it is inconceivable that any inventor could have intelligently devised the Atkinson cycle for gas engines had he not been guided by thermodynamics. The mistaken ideas which are held by some engineers in regard to thermodynamics arise from the erroneous notion that the principles of the science are identical with complex mathematical analysis. We feel sure that if such engineers were aware of the close relation which exists between this science and every item of economy in the working of their engines, there would be a higher and more adequate appreciation of its value.

That there is not in Prof. Ewing's book anything of the nature of a discovery or advancement of new thermodynamic principles is not, on the other hand, a fact which should make it any the less useful to the student. Prof. Ewing has exercised the most commendable judgment and care in his selection of subject matter. The details of thermodynamics with which he deals are just such as are essential to a broad-minded knowledge of engineering; nothing that can be considered as such has been omitted, while nothing of a purely physical nature irrelevant to engineering has been introduced. It is chiefly in this respect that the student will value Prof. Ewing's book, as compared with the more comprehensive and less strictly engineering treatises of Clausius, Cotterill and Maxwell. Then again, Prof. Ewing exhibits a clear and easy style, avoiding wherever possible the higher mathematical walks, and he considerately assumes that his reader is one who does *not* know all that he is reading rather than one who does. Finally, the treatment of well-established thermodynamic principles has received considerable development of late; and Prof. Ewing has not failed to bring his treatise up to date in this respect. Thus we find a full account of the graphic methods of studying the functions of entropy and temperature, and some recent graphical constructions dealing with valves. In connection with the former of these instances, we cannot refrain from expressing our regret that the classic symbol, θ, for absolute temperature, should have been abandoned. We were all learning to speak of "the θ ϕ diagram" as an established mathematical instrument.

The work commences with a chapter on "The Early History of the Steam Engine," which passes in brief review the various ancient engines, from the Egyptian dodge for impressively opening a temple door before an astonished crowd down to the inventions of Watt and Stephenson. In our opinion, considering the fact that the subsequent parts of the book are not devoted to the structure of engines as a whole, as well as the fact that only a single chapter is devoted to "Air, Gas and Oil Engines," this chapter might well have been omitted or compressed to within a much smaller compass. In the next chapter the elementary principles of thermodynamics are considered, the reader being introduced to the two laws of thermodynamics and their relation to physics, and to the action of any working substance. Chapter III. deals with the production and thermodynamic properties of steam. It is regrettable that the table of the properties of saturated steam on page 65 is not presented in a more handy form. It is evidently compiled from a similar table which contained a temperature column in centigrade degrees, for the temperature column on page 65 consists of intervals of 9° F. throughout, a by no means convenient interval. In Chapter IV. some of the most important thermodynamic problems, such as the relations of entropy to temperature under various operations, are considered. The next chapter, on the "Actual Behaviour of Steam in the Cylinder," is one of the best in the book, and is remarkable for the masterly way in which the bearing of the various theoretical deductions upon actual practice is developed. In this chapter the influences of wetness, wire-drawing, clearance, compression, jacketting, superheating, various cut-offs, &c., &c., are very clearly discussed. The chapter on "The Testing of Steam-Engines," which follows, is brief and complete; and, though accurate as far as it goes, it is not one which will prove of much practical value to the engineer. Fourteen pages are quite inadequate to the proper treatment of such an important subject. Chapter VII. deals briefly with "Compound Expansion," and is devoted to considerations of the behaviour of steam in Woolf and receiver engines, and to the combination of indicator cards taken from these engines. The next two chapters are the only ones which are devoted to considerations of mechanical details of steam engines. The former of these is on "Valves and Valve-Gears," and the latter on "Governing." The simple slide valve comes in for a large share of attention, and is discussed by several graphic methods, including the well-known Zeuner polar curves and the oval diagram. As a variant upon the latter, a graphic construction involving the plotting of sine curves on rectangular axes is given and recommended as "a much more useful diagram." Undoubtedly it is a very interesting diagram, but we are inclined to think that steam engineers are not so fond of plotting sine curves as are their electrical brethren, and that they would prefer less mathematically elegant but more handy methods of determining valve quantities. As a classroom device for explaining valve relations, however, the construction might be found useful. Chapter X., on "The Work on the Crank-Shaft," discusses the variations of crank effort, the influence of the fly-wheel, and balancing. The treatment is on the orthodox lines of rigid dynamics, and somewhat *doctrinaire.* Not until Chapter XI. is reached is there any attempt to discuss the practical generation of steam in boilers; and we think that the student must be placed at a disadvantage in his study of the foregoing chapters from the tardiness with which he is informed of the action of boilers in producing steam, and of the character of the steam they are liable to produce. Some of the most important boilers are described, and the chapter is well illustrated.

A good practical chapter follows, on "Forms of the Steam Engine." It is scarcely necessary to say that only a very few forms are described, because in a work having so great a scope it would be impossible to give an exhaustive account of even the most important types. The beam engine is the first described, followed by a summary of the advantages and characteristics of direct-acting engines. Single-acting high-speed engines are represented by the Brotherhood 3 cylinder engine and the Willans engine. Vertical non-rotative pumping engines and the pulsometer are briefly described; and a short account is given of the Davey safety motor, or the "kettle engine" as someone has aptly called it. Rotary engines and steam turbines are represented by the Tower spherical engine, of which one hears so little now, and the Parsons engine, the latter being very fully discussed. Marine and locomotive engines complete the chapter, and receive brief description. A short concluding chapter on "Air, Gas, and Oil Engines" may perhaps be considered to justify the use of the phrase "other heat engines" in the title of the book. This chapter upsets the balance of the whole book; for, from a theoretical point of view, the "other heat engines" deserve far better recognition; and if, from the practical point of view, the steam engine is worthy of so great a share of consideration, it must be objected that Prof. Ewing's treatment of the steam engine is not at all from the practical point of view. There can be no excuse, therefore, for crowding the account of the non-steam heat engines into one short chapter. The hot-air engines of Stirling, Ericsson, Robinson, and Buckett, are discussed. Then follows some account of the work of Beau de Rochas and Otto, in connection with gas engines; trials of modern gas engines and the use of cheap gas fuels are next considered; and the chapter concludes with a page or two on oil engines.

The engineering student has cause to be thankful to Prof. Ewing for this book. It is one that cannot fail to take its place among standard educational works that every student of theoretical engineering should possess.

The Art of Soldering. By William Probert. (Municipal Technical School, Birmingham.)

It is impossible to discuss the whole art of soldering in a little pamphlet of 22 pages, but the author has put together some very useful notes on the chemistry of fluxes, the composition of hard and soft solders, and gives a few practical hints about their use. The dodges peculiar to electrical work are not mentioned; but even those electricians, and there are many, who can handle a bit or blowpipe in a way that astounds an ordinary tinsmith, and can achieve feats of soldering which no workman would have believed possible a few years ago, will find something worth knowing in Mr. Probert's little book.

THE WORK OF HERTZ.

CORRECTIONS AND EXPLANATIONS BY DR. OLIVER LODGE.

In connection with the illustrations to a lecture of mine at the Royal Institution, recently reported in *The Electrician*, June 8th, 15th, 22nd, there are some misapprehensions which it may be well to set right for the benefit of students and others who may wish to repeat some of the experiments. Many of the experiments lend themselves to easy repetition, since they involve nothing novel in the way of apparatus except what is quite easily constructed; many of them can be performed with the ordinary stock apparatus of an amateur's laboratory.

Figs. 2, 3, and 4 (page 154) are curves obtained by Bjerknes with the apparatus depicted in Fig. 14, which is intended to show:—

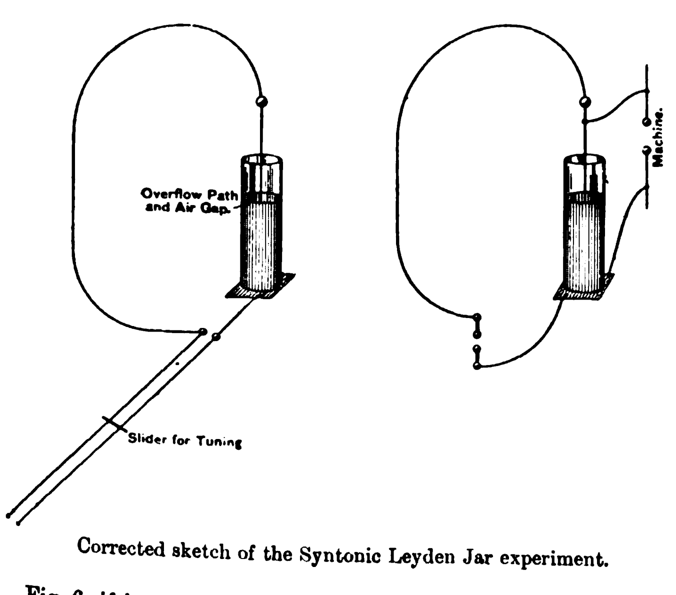
(1) A Hertz vibrator connected to an induction coil;

(2) A nearly-closed-circuit receiver properly tuned with the vibrator; and

(3) A one-sided electrometer for inserting in the air-gap of 2.

The receiver is not provided with knobs, as depicted in Fig. 14, but its open circuit is terminated by the quadrants of the electrometer, which is shown on an enlarged scale alongside. The needle is at zero potential and is attracted by both quadrants. By calculation from the indication of this electrometer Bjerknes plotted the curves Figs. 2, 3, and 4. Fig. 2 represents the oscillations of the primary vibrator, rapidly damped by radiation of energy. Fig. 3 represents the vibrations thereby set up in the resonating circuit when the two are accurately in tune; and which persist for many swings. Fig. 4 shows the vibrations excited in the same circuit when slightly out of tune with the exciter. A receiver of this kind makes many swings before it is seriously damped.

In Fig. 5 the emitting circuit is properly shown, but the receiving circuit is not shown properly. The following sketch is correct.



Corrected sketch of the Syntonic Leyden Jar experiment.

Fig. 6, if its plates and rods are magnified enormously without magnifying the knobs, may serve to represent the gigantic vibrator mentioned on pages 186 and 187; whereas the ordinary-size Hertz vibrator is shown in Fig. 10, on a scale of about an inch to a foot.

A new figure, Fig. 22, may be added instead of the last footnote on page 155, to illustrate the arrangement by which I showed the effect on one spark of the light from another. It will be observed that with this arrangement the B knobs are at the same potential up to the instant of the flash, and in that case the ultra-violet portion of the light of the A spark assists the occurrence of the B spark. But it is interesting to note, what Elster and Geitel have found, that if the B knobs were subjected to steady strain instead of to impulsive rush—*e.g.*, if they were connected to the inner coats of the jars instead of the outer coatings—that then the effect of ultra-violet light on either spark gap would exert a deterrent influence, so that the spark would probably occur at the other, or non-illuminated, gap. With the altered connections it is of course not feasible to illuminate one spark by the light of the other; the sparks are then alternative not successive.

The work of Elster and Geitel ought to have been mentioned in the penultimate paragraph of p. 155, but the omission is repaired in a separate article which is shortly to appear in *The Electrician.*

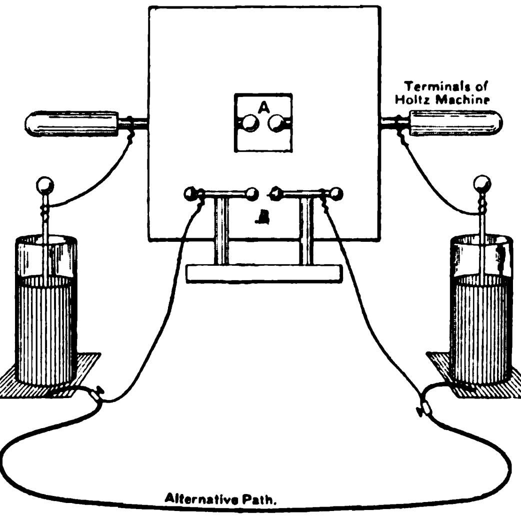


Fig. 22.—Experiment arranged to show effect on one spark of light from another. The B spark occurs more easily when it can see the A spark through the window, unless the window is glazed with glass. A quartz pane transmits the effect.

With reference to the silent discharging power of light for negative electricity from clean metallic surfaces, Fig. 6 is drawn much as the experiment was shown; it being understood that the lenses are of quartz, not glass. But there is no need to condense the beam at all in this experiment, the naked arc acts powerfully on clean zinc or aluminium, or, indeed, on most metals. But if there be a few minutes' delay after sandpapering the surfaces the effect is very noticeably diminished. In Fig. 8 all the optical parts are of quartz, and the position of the zinc sphere indicates its position in the most effective region of ultra-violet light.

A few lines below Fig. 9 the references in the text have got mixed; the reference to Fig. 9 should be to Fig. 10, and the reference to Fig. 10 should be deleted. The knobs of Fig. 11 should be nearly in contact. Fig. 12 is not a resonator or receiver, but an emitter; it emits a long series of 3in. waves at each spark, and it was arranged against the *outside* of a tinfoil-lined box containing battery and induction coil for exciting it. Alongside of it and outside the same box was arranged the larger radiator, Fig. 20, the wires from which pass into the box through glass tubes, and are there connected with the terminals of the secondary coil. The object of this metal-lined box or packing-case is to keep in all the stray waves, which else are liable to start from any part of the circuit; *i.e.*, to insure that the ostensible source shall likewise be the real one. The sending arrangement shown in Fig. 21 would do very well, but the box should be of metal. The wires of the receiving circuit are screened from direct radiation by being inclosed in a compo pipe.

Fig. 18 does not represent what I have called a coherer, but a simple tube of iron borings or filings, as used by me following M. Branly. Fig. 17 is the coherer, though the spiral should be longer to give elasticity enough, and no "stop" is desirable as the pressure has to be regulated by trial. The contact best adapted for sensitiveness is one with quite appreciable pressure. Some practice is needed to work with these things.

The spherical radiator shown in Fig. 19, which was at pleasure either two inches or five inches in diameter, though it could excite the filings tube Fig. 18 when 60 yards away in the open air, yet could not excite it perceptibly when screened off by so many walls and metal surfaces as exist between the Library and Theatre of the Royal Institution. It could, however, still easily excite the coherer, which is immensely more sensitive, and also more troublesome and occasionally capricious than is a tube of iron filings.

In Fig. 16 the handle should be shown of ebonite too, to permit a delicate adjustment without discharge. The instrument is intended to be placed on, or otherwise connected with, the cap of an electroscope, while the left hand terminal is connected to its sole or outer case. Any electrification then given to the right hand screw soon causes overflow at the excessively minute spark-gap inside. The leaves only diverge a little way and then suddenly collapse.

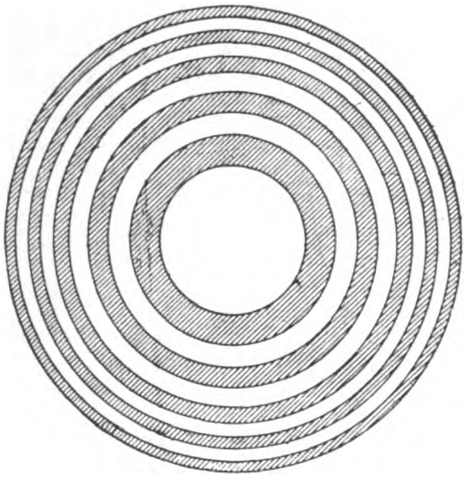

Fig. 23.—Zoneplate of Tinfoil on Glass.

A zone plate or series of rings of equal area, made of tinfoil pasted upon glass with alternate spaces bare, is shown in Fig. 23 herewith, and is intended to act as a diffraction lens, concentrating to a focus the 3in. waves from the radiator Fig. 12.

Lastly, a table of numbers interpolated in the second column of page 204, beginning "with reference to the reflecting power. . . ." and ending "up against stops," is seriously out of its place, since it interrupts the sense of another paragraph. It belongs properly just above the first italic heading on page 205.

The account of the "optical experiments" given towards the end of the lecture is very compressed. It may be well to give a few additional remarks on this subject in another article.

ARC LIGHTING AT HASTINGS.

On Saturday last the occasion of the first lighting up by arc lamps of the entire length of the Hastings and St. Leonards sea front and promenade, extending from the extreme easterly point, known as the Fish Market, to the west end of the Marina, was appropriately celebrated. After a banquet, given by the Hastings and St. Leonards Electric Light Company, at which the Mayors of Hastings and Winchester and a number of other gentlemen were entertained, the invited company proceeded to the end of Hastings Pier, where the Mayor of Hastings formally switched on the long line of arc lights. The company then made a closer inspection of the lighting by driving along the sea-front.

For many years a certain amount of arc lighting has been done at Hastings by Brush continuous-current lamps, supplied in series from Brush dynamos, and the ordinary house lighting has been worked on the alternating-current transformer system. This practice entailed the use of two distinct sets of plant at the generating station, and rendered it impossible to combine the two loads, at least as far as the engines and dynamos were concerned. Upon the extension of the public lighting from the original 15 lamps, occupying little more than half a mile of sea-front, to the present 52 lamps, extending some two and a-half miles, it was very wisely determined to so arrange matters that the steady arc light load might be put on the same generators as would be used for the house supply, thereby materially improving the load factor and economy of the station. The work of carrying out these alterations and extensions was undertaken by the Brush Electrical Engineering Company, who have succeeded in turning out the work in an effective and thoroughly satisfactory manner. Contrary to the teachings of those who maintain that the continuous current arc in-invariably gives the best results in street lighting, the conditions on the sea-front seem to be such as are favoured by the use of the alternate current arc. The light, which is thrown upwards, strikes pleasantly against the upper portions of the houses which skirt the sea-front, and in this way an effect more generally resembling the even distribution of daylight is produced.

Each lamp is fed from a separate transformer, this latter taking the primary power at 2,000 volts and transforming it down to 50 volts. A small choking coil placed in the lamp circuit serves to regulate the voltage on the arc. The transformers of the 52 lamps are grouped in parallel on two pairs of mains, the connections being so made that the failure of either main will extinguish only alternate lamps. These two mains are switched on to the station bus bars, being fed at 2,000 volts from the Mordey-Victoria alternators, which also supply the house mains. The alternators are rope-driven by Raworth steam engines. The contracting company have been ably assisted in carrying out this work by Mr. M. G. Ross, the engineer and manager to the local company, and by Mr. E. Geipel, the resident outside engineer, and all parties connected with the enterprise are to be congratulated on this successful piece of work.

HEINRICH HERTZ.*

The first day of this year took away from us a fellow worker whose loss affects us most deeply. If, after a long career of discovery and a life rich in achievements, one of the old masters of science passes to his rest, we lament his death but we bow to the inexorable laws of nature. In Heinrich Hertz a discoverer of the first rank has been torn away from us in the middle of his work, and almost at the commencement of the prime of life. The sad news has spread far and wide, and so it is very fitting that we also should pay a tribute to his memory. Let us first glance over the development of the external events of his life during the short space of time allotted to it.†

Heinrich Rudolf Hertz was born at Hamburg on February 22, 1857, and was the eldest son of the then attorney (and later Senator) Hertz. His mother was a native of Frankfort-on-Main. After having attended a city school until his confirmation, he studied privately at home during the years 1873-4, and at Easter, 1874, he entered the highest class of the upper school of the Johanneum in his native town. At Easter, 1875, he left school, in his eighteenth year, with a certificate of fitness for the University.

Even as a boy he displayed great talent, but more especially a strong liking for, and an uncommonly great interest in, the exact sciences. As a scholar of twelve years of age he attended Sunday classes in geometrical drawing held at the Technical School. In addition to his scholastic studies he industriously practised the use of tools, and he went through that course of practical training in carpentry and lathe-work which is of so great importance to the physicist; his skill enabled him to construct quite serviceable instruments from the simplest materials, and, among other things, he once made for himself a spectroscope.

* Memorial Address by Prof. Hermann Ebert, delivered at the meeting of the Physical Society of Erlangen, March 7, 1894. Translated by James L. Howard.

†For the following biographical notice the author acknowledges his deep indebtedness to Frau Prof. Hertz.

Digitized by Google

When he left the Gymnasium it became necessary for him to choose a profession. His desire to construct something useful and permanent and his innate modest temperament, which at that time caused him to doubt greatly his ability to accomplish anything satisfactory in pure science, as well as his newly-awakened joy at the prospect of making a practical trial of his powers, all these led him to choose the profession of an engineer, and, indeed, that of a civil engineer. As a preparation for this calling he served during the year 1875-6 as an apprentice in the city engineer's office at Frankfort-on-Main, such preparation being at that time a necessary preliminary before entering the profession. After this he went during the Summer Semester of 1876 to the Technical High School at Dresden. During the twelve months subsequent to October, 1876, his studies were interrupted by his year of military service, which he passed at Berlin in the Railway Regiment. In the autumn of 1877 he went to Munich. This was the most remarkable turning-point in Hertz's career, which converted him from a man of practice to one of learning. Here he recognised that his nature could only find full satisfaction in dealing with science, and he applied himself in Munich specially to mathematics and physics.

After only a year, in the autumn of 1878, he removed to the University of Berlin, where he entered the laboratory of Von Helmholtz. His progress was unusually rapid. In 1879 he gained a prize offered by the Philosophical Faculty for a research on extra currents induced in coils and wires, a work which presented difficulties both of theory and experiment. In 1880 he graduated as doctor, and in the same year Von Helmholtz chose him as assistant in the Physical Institute, only three years after he had first devoted himself to the study of physics.

At Easter, 1883, when in his twenty-sixth year, he became Privat-Docent at Kiel, acting on the advice of Von Helmholtz, and he immediately obtained a commission to teach theoretical physics from the Prussian Minister of Instruction. At Easter, 1885, when twenty-eight years of age, he received a call as ordinary Professor of Physics at the Technical High School at Karlsruhe. From this place originated his epoch-making experimental researches. In 1886 he married Elizabeth Doll, daughter of the Professor of Geodesy at the same High School.

When in the year 1889 death took away from Bonn Clausius, the founder of the mechanical theory of heat, there was no hesitation in conferring upon Hertz, although only thirty-two years of age, the honour of succeeding a Clausius; and at Easter, 1889, he was called to Bonn.

Having thus succeeded to a secure and honourable position, respected and admired both in Germany and abroad, at an age when the power of research usually first begins to make itself manifest, he was soon visited by the insidious enemy which was destined to bring so brilliant a career to such a tragic close. In the middle of the year 1892 a chronic blood-poisoning, originating, probably, from a gathering in the jaw cavity, had already begun to undermine his hitherto excellent health. The crisis, which occurred in November, 1892, was passed by a successful operation, and he was able to continue his lectures throughout the Summer Semester of 1893, and (although with great effort) until December 7th of the same year, only a short time before his decease. His malady then returned, and in a few weeks proved fatal; he died on New Year's Day in the 37th year of his age. According to the testimony of those who were near him, and particularly of his wife, who nursed him faithfully to the last, his sufferings were indescribable. In him there passed away not only a man of great learning, but also a noble man, who had the singular good fortune to find many admirers, but none to hate or envy him; those who came into personal contact with him were struck by his modesty and charmed by his amiability. He was a true friend to his friends, a respected teacher to his students, who had begun to gather round him in somewhat large numbers, some of them coming from great distances; and to his family he was a loving husband and father.

The course of events in the external life of Heinrich Hertz was simple and plain. But what a world is opened before us when we consider his scientific life, which was bound up within such narrow limits of time! To give a condensed sketch of its development is the object of the present address.

We generally speak only of his later epoch-making researches; they alone have become known far and wide. But it is very instructive to glance once more over the earlier researches from the higher standpoint reached by the later ones. Further, we perceive how the later discoveries, which have transformed the whole subject, were originated and developed from the former, these being in a certain restricted sense stepping-stones to the latter series of experiments, for Hertz was not led by mere accident to his investigations on the propagation of electric waves; it was a comprehensive and well-arranged process of argument which was crowned by those researches, even if a happy chance often furnished him with the means of more quickly reaching the goal. I shall confine myself to the electrical researches, and therefore merely mention Hertz's work on the evaporation of liquids and in particular of mercury in vacuo, on the pressure of saturated mercury vapour, his meteorological investigations, his researches connected with elasticity, and the theory of solids; these all show the many-sidedness of his work.

His scientific activity began, as we have already seen, with the solution of a prize problem. The research proposed by the faculty of the University of Friedrich Wilhelm at Berlin for the students of 1879 was the experimental investigation of the intensity of induced electric currents. The problem, the solution of which was intended to be advanced by this research, was an old one, and for the older theories of electric phenomena a very important one. These theories were based on the assumption that electricity was a fluid which moved through the conductor conveying it. If anything of the nature of matter was concerned in electric phenomena this hypothetical something must possess *mass*, even if only in a small degree. If it had mass it must possess inertia when subjected to "electromotive forces," and must therefore, when once set in motion, contain a certain amount of kinetic energy by virtue of its mass and velocity. This kinetic energy would manifest itself if the current in a coil were alternately suddenly made and interrupted; because "extra-currents" are then set up in the coil in consequence of the mutual inductive action of the separate parts on each other, and the energy of these extra-currents would represent that of the moving electrical masses. An exact numerical estimate of this energy, and hence of the quantity of electric fluid, say, in a cubic millimetre of a wire traversed by a current, was hardly to be expected because of the difficult nature of the measurements; one had to be content with seeking an upper limit for the quantity of energy and thus furnishing an answer to the question "How great can this quantity of energy possibly be?"

The first considerable experimental investigation of Hertz was devoted to this problem. It appeared with the title "Experiments to determine an Upper Limit for the Kinetic Energy of an Electric Current." The result of the experiments was negative; since the upper limit became smaller and smaller the more exactly the experiments were performed, it was necessary to conclude that the quantity looked for would also eventually become zero if all errors of experiment could be successfully eliminated. But it was certainly a matter of great importance for Hertz that in his first research in the domain of electricity he already convinced himself that assumptions as to the material nature of electricity were untenable, and that the postulated fluid vanished just as he sought to detect it with more accurate means of observation.

In this first work, published when he was only twenty-two years of age, great experimental skill was displayed. We find him working with long stretched wires and large wire rectangles which he stretches in the cellar of the laboratory, pieces of apparatus which he was destined to use later in such a masterly fashion as his tools. One particularly clever device was the arrangement of a commutator by the simple rotation of which a complicated system of conductors could be automatically and quickly inserted in the circuit, cut out or reversed, in regular order. That Hertz was even then master of the mathematical theory, that most important adjunct to his work, is shown by his calculation of the action of the various turns and layers on each other; that is to say, by his calculation of the self-induction of his coils.

Hertz returned to the same subject again at the end of a year ("Upper Limit for the Kinetic Energy of Electricity in Motion"), when he employed a method which was not only more direct and more sensitive, but at the same time more perfect in its theory. A very thin silver film deposited chemically on glass was traversed by a strong current in one direction; the current-density, or, according to the older theory, the amount of moving electricity in each cubic millimetre of silver, was in this case as great as possible. If this moving electricity was only subjected to the electromotive force of the voltaic cell driving it, the plate was traversed by it symmetrically from anode to cathode; and if two wires leading to a sensitive galvanometer touched the plate at points on a line perpendicular to that joining the electrodes, no current would pass between these wires. The plate was now fixed on a whirling-table and rapidly rotated about an axis through its centre perpendicular to its plane. If moving electricity possessed any property analogous to inertia the current would be deflected by this rotation out of its original path, just as currents of air moving over the surface of the earth from the equator to the poles are deflected by its rotation from their south-to-north direction and strike the meridians at an angle. In this case a component of the current would pass between the two transverse electrodes, and this would be indicated by the galvanometer, even though only small in amount. Numerous sources of error, thermal currents caused by unequal heating of the two electrodes by the air currents, alterations in the rotating plate due to centrifugal force, &c., all these were encountered and to some extent masked the effect looked for. But Hertz knew how to reduce these sources of error to a minimum by a judicious combination of separate experiments under varying conditions. In spite of this, 320 separate observations failed to give any positive result; the upper limit so determined is that the kinetic energy of an electric current whose density (measured electromagnetically) is

Digitized by Google

unity is, per cubic millimetre of a silver film, not so great as that of $\frac{1}{50000}$th of a milligram moving at the rate of a millimetre per second. At the end of this Paper he points to the possibility of obtaining positive results in the case of electrolytes, in which the motion of the electricity is bound up with that of the material ions. This conjecture of Hertz has been confirmed by later researches of Colley and Descoudres. Here, however, it is not the inertia of electricity itself, but that of the bodies carrying it, by which the phenomena are brought about.

His thesis for the degree of Doctor in 1880 treats of induction in rotating spherical conductors or hollow spheres between magnets according to the theory of Neumann.

(*To be continued.*)

DIRECT-READING APPARATUS FOR THE DETERMINATION OF THE MAGNETIC QUALITIES OF IRON.*

BY DR. A. KOEPSEL.

The author, who is the designer of the apparatus described, having set out with the idea that for a direct-reading instrument an incomplete magnetic circuit must necessarily be employed, began by the investigation of two points: first, whether results could be obtained with an incomplete magnetic circuit which could

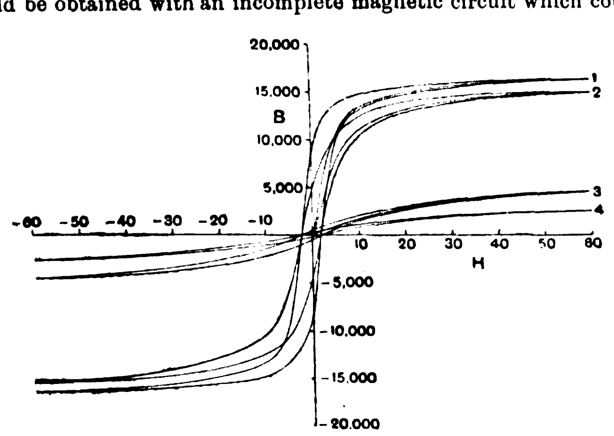

Fig. 1.

be definitely referred to those obtainable with a closed circuit, so that the latter could be easily deduced from the former; and, secondly, whereabouts in an incomplete circuit is the best position for the division, with the object in view of getting the magnetisation curves as correctly as possible. A division in the sample itself was found to be out of the question, as even when the pieces were pressed tightly together a considerable alteration of the curve of magnetisation was observed. Fig. 1 shows in curves 1-4 the

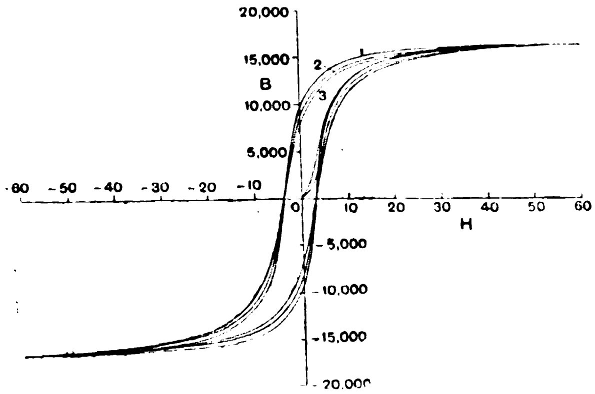

Fig. 2.

curves of magnetisation obtained by the ballistic method from a bar of soft iron 6mm. in diameter, the return being by a large yoke, the curves referring to the following cases:—(1) The bar whole and undivided; (2) The bar cut in two, and the surfaces pressed tightly together; (3) The surfaces 1·3mm. apart; (4) The surfaces 2·5mm. apart.

On the other hand, a division in the yoke itself had comparatively little effect, as shown in Fig. 2, curves 1-3, which represent the curves of magnetisation of a similar bar under the following conditions:—(1) With an undivided yoke; (2) Yoke divided, and the surfaces pressed tightly together; (3) The surfaces 1mm. apart. As the yoke had 100 times the surface of the sample, the magnetic resistance of the division was 100 times as small as in the first case. It is then of great importance to get the yoke as large as possible, which was done in the author's case by making the yoke a solid of rotation, which one can imagine formed by rotating the yoke

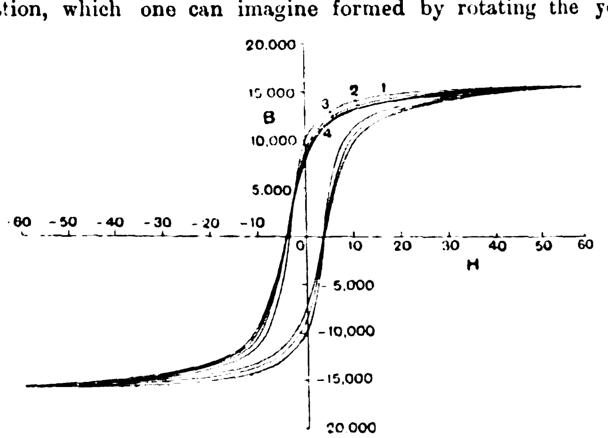

Fig. 3.

about the test bar as an axis, the bar and the magnetising coil being thus completely enclosed. It was then found that, although the curve obtained by pressing the half cylinders together (No. 2, Fig. 3) was not the same as that obtained with an undivided yoke (No. 1), yet the latter could be obtained from the former by the shearing process; and, further, the experiments showed that a gap of 1·5mm. between the cylinders did not very much alter the form and position of the curves (Nos. 3 and 4).

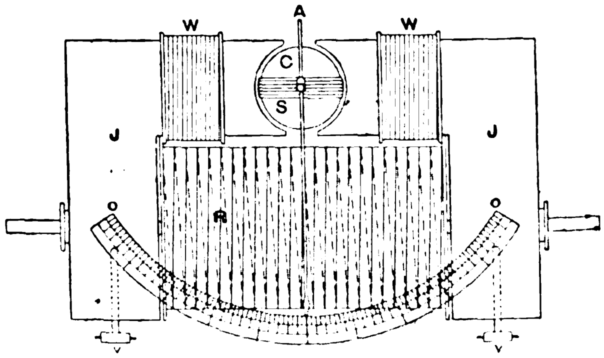

Fig. 4.

A gap of 5mm., however, was enough to afford room for a flat-wound coil carrying a current and controlled by a torsion head, the amount of whose rotation to bring the coil to zero is a measure of the field. This coil, however, had to be made very small, and had, consequently, a very small torque; and therefore a design had to be evolved which, while not increasing the air space, should allow of a larger area of coil. This object was attained by return-

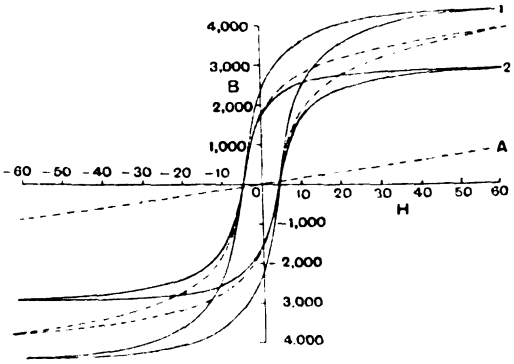

Fig. 5.

ing to the simple form of yoke shown in Fig. 4. The yoke J is bored out at A like the pole pieces of a dynamo, and the piece bored out is replaced by a soft iron cylinder, C, having a diameter 2mm. less; and in the cylindrical air space so made a coil is placed, working on pivots, and capable of rotation, and which is traversed by a current of about 0·01 ampere led in by palladium springs. The openings *o o* of the yoke serve for the introduction of the

* *Elektrotechnische Zeitschrift.*

Digitized by Google

samples, which may be bars or sheets. These are fastened by means of the screws r, and suitable clamping pieces. The test piece is completely surrounded by the magnetising coil R, which is so wound that the magnetising force is exactly one hundred times the current in amperes. In order to counteract the effect on the swinging coil of the induction produced in the yoke by the magnetising coil when no test piece is in place, the coils W W are wound on to serve as compensating coils. Another simple method is to magnetically short circuit the magnetising coil by a suitable iron covering.

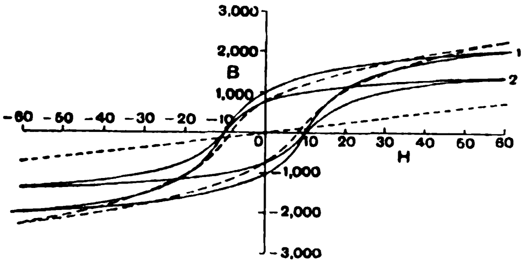

Fig. 6.

The apparatus was then carefully calibrated by ballistic measurements in the centre of the bar and the centre of the yoke (*see* Fig. 5), and it was found that Curve 1 (obtained on the bar) could be deduced from Curve 2 (obtained at the yoke) by simple multiplication of the ordinates by the factor 1·47, the coefficient of leakage, with a considerable degree of accuracy. The dotted curve shows the values obtained actually in the middle of the yoke when the effect of the coil on the yoke itself is not deducted. This coefficient of leakage was the same for wrought and cast-iron

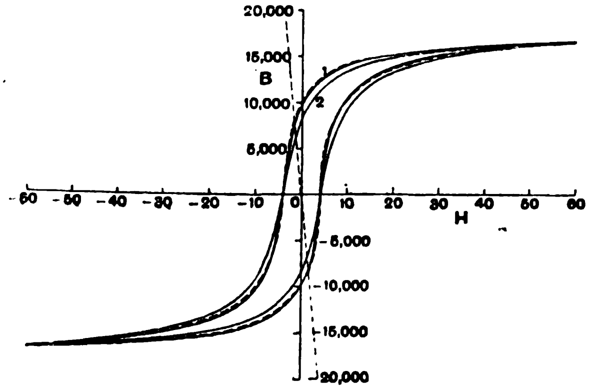

Fig. 7.

(Fig. 6), and it was, therefore, possible to calibrate the apparatus so that the pointer indicated directly the value of the induction density for different kinds of iron. It will be noted that it is unnecessary even to have test bars always of the same section, for the current in the swinging coil may be adjusted for any required section so that the scale is direct reading, and this operation has only to be performed once, before the determination of the curve is begun. It is, of course, assumed in doing this that the resistance of the yoke is negligible compared with that of the bar, which is

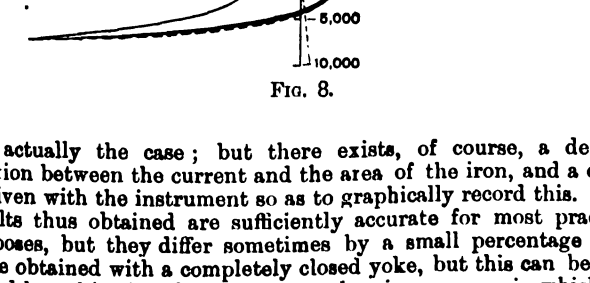

Fig. 8.

not actually the case; but there exists, of course, a definite relation between the current and the area of the iron, and a curve is given with the instrument so as to graphically record this. The results thus obtained are sufficiently accurate for most practical purposes, but they differ sometimes by a small percentage from those obtained with a completely closed yoke, but this can be corrected by subjecting the curves to a shearing process, in which the line of shearing may be taken as straight up to about 12,000 C.G.S. units of induction. For higher values the line of shear is curved, and can be determined once for all for every instrument. This curve may be rendered approximately a straight line by somewhat under-compensating, but this only has the right effect if the sectional area of the iron bar be kept constant.

The author is making further experiments in which the coil is replaced by a notched-armature, so as to reduce the air-space to half a millimetre, and the induction is to be measured by rotating the armature at a given speed and observing the volts on the armature.

The Figs. 7, 8, and 9 show the agreement of the curves obtained with those obtained by ballistic measurements. In each case Curve 1 is the ballistic curve, Curve 2 the one obtained from the under-compensated apparatus, and the dotted curve is the latter corrected by shearing with a straight line as the line of shear. Fig. 7 refers to wrought-iron bars, Fig. 8 to cast-iron, and Fig. 9 to charcoal iron plates.

The ballistic measurements were carried out by the aid of an astatic mirror galvanometer, whose constant was controlled before every experiment by means of a standard condenser. For if a condenser be discharged through a galvanometer, the deflection

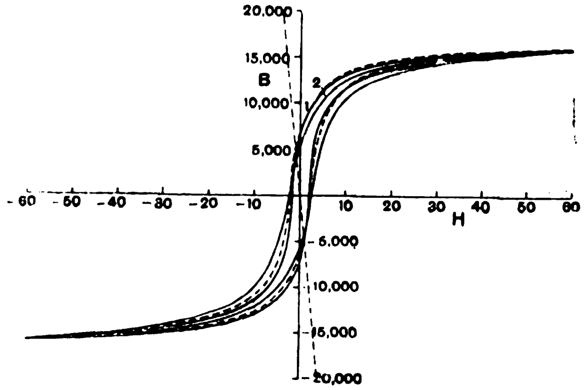

Fig. 9.

$\delta = a \cdot K V$, where K is the capacity, V the electromotive force with which it is charged, and a the galvanometer constant. If the ends of a coil of wire of one square centimetre area be connected to the terminals of the same galvanometer, and B lines of induction be sent through the coil, the deflection

$$\delta_1 = a \, B / W,$$

where W is the resistance of the circuit. Combining these equations the constant disappears, and we have

$$B = K V W \delta_1 / \delta.$$

If expressed in the practical units, this must be multiplied by 10^2. Damping may therefore be neglected so long as the deflections remain proportional to the electromotive force of the condenser. The self-induction introduces an error, and it is well to take a galvanometer of small number of turns, or to put a large inductionless resistance in the circuit. In conclusion, the author remarks that apparently the same idea has occurred to Mr. L. F. Robinson, who speaks of it in the *Electrical World*, February 24, 1894; but the latter gentleman does not appear to have ever made the apparatus.

A COMPARISON BETWEEN AMERICAN AND GERMAN CENTRAL STATION STATISTICS.*

The value of reliable statistics properly classified and digested is too well known to require special pointing out; but it is sometimes forgotten that they are especially valuable when relating to new industries, such as electric lighting and power distribution. Various attempts have been made by the National Electric Light Association to supply this very necessary data, but the work thus far accomplished must be regarded as but a tithe of that necessary to enable the central station manager to compare the operation of his own station with that of others. Thus, at the last Convention held in Washington the statistics submitted were limited practically to the consumption of coal per horse-power hour in central stations. This was good enough in itself, but manifestly it covered but a part of the working of a central station.

In marked contrast to the American lack of data in this respect are the statistics from Germany. We have before us two statistical compilations, one embodying the work of the German Elektrotechnischer Verein and the other that of the "Free Association of Electric Light Station Representatives." Naturally both sets of statistics cover much of the same ground, but they differ somewhat in their modes of tabulation and each has a distinct value of its own.

* Abstract from the *Electrical Engineer* of New York.

Digitized by Google

That of the Electrotechnischer Verein gives the tabulated results of central stations in 24 cities, including four having over 250,000 inhabitants, seven between 75,000 and 250,000, seven between 10,000 and 75,000, and six under 10,000. These stations employ probably all the various ordinary methods of generation and distribution, and allow some quite definite conclusions to be reached on hitherto doubtful points.

Comparing the cities for current capacity installed per 1,000 inhabitants, we find it to vary considerably, and, as would hardly be expected on first consideration, to average higher in the smaller cities than in the larger ones. It amounts in Berlin to 5·81 kilowatts per 1,000 inhabitants. A glance at the cities of the third group shows that the consumption of current is largely increased by the adoption of a sliding scale. The proportional distribution of lighting in hotels, dwellings, theatres, &c., varies, of course, with the character of each city. Thus, whereas in Berlin the percentage of current furnished to dwellings and hotels is only 19·9 per cent. of the total consumption, it amounts to 38·7 per cent. in Hamburg. A greater constancy in this respect is shown in store illumination, at least in the larger cities, where 30 per cent. of the total is about the average of current consumed in such places. This is in marked contrast to the figures in the United States, in which hotels and private dwellings represent but a small fraction of the current consumed, by far the largest percentage being devoted to store and office illumination. This fact is due, in part, probably to the larger number of isolated plants in the United States. Factory lighting represents but a small fraction of the whole, which is easily accounted for. Unfortunately, the data on street illumination is incomplete, so that no comparison can be made in this respect.

The amount of electric power consumed in German cities is of special interest. From the tables it would seem that the cities of medium size employ but very small quantities, whereas the larger cities take proportionately more current for this purpose. Thus Berlin and Vienna employ, respectively, 8·6 and 6·8 per cent. of the total current generated for power purposes. Glancing at the actual electrical energy consumed we note that Berlin stands at the head with 6,700,000 kilowatt hours per annum, followed by Vienna with 1,300,000; then comes Hamburg with 500,000, and Dusseldorf and Elberfeld with 300,000 each.

The charges for current in Germany show a most varied practice. A fixed charge per lamp installed is exacted in Berlin and Innsbruck. In Vienna-Mariahilf this charge is waived beyond 100 lamp hours per lamp. In Heilbronn a charge is only made for the first 10 incandescent lamps or the first 2 arc lamps; in the first case $1. 87c. (about 7s. 6d.), and in the latter $10 (£2). A sliding scale is in vogue in several cities. The cheapest rates are to be found in Triberg, where the lamps are divided into three groups. The first group includes such lamps as are burnt in winter and summer at definite times; the second, lamps which are burnt only in winter or only in summer; and third, lamps which are used temporarily only. The prices are also graded according to whether the lamps are used in hotels, dwellings, stores, or factories. There result from this no fewer than 12 different rates of charge, varying from $9 (£1. 16s.) to $90 (£18) per kilowatt per annum.

The average price of current in stations selling by meter is a little over 18c. (9d.) per kilowatt hour, the highest being 22½c. (1s.); but the discounts vary considerably in different localities. The rates for electric power are arranged on a variety of plans. In Düsseldorf and Hamburg each case is treated individually and a special price fixed. In other cities there are flat rates without discount, as in Barmen, Berlin, Stockholm, and other cities. The highest price is that in vogue at Gummersbach, namely, 13c. (6½d.) per kilowatt hour. In Berlin, however, the low price of 5c. (2½d.) obtains, while at Triberg power is actually sold at 2½c. (1¼d.) per kilowatt hour. It goes without saying that current for power purposes can be furnished at a lower cost than for lighting, but one is hardly prepared for such generally low prices as these statistics show. For those who argue that the electric light and electric power are luxuries, the German statistics will prove a revelation. They show, in fact, that in the larger cities electric light is but slightly dearer than gaslight; but that electric motive power is still considerably dearer than gas-engine power, leaving out of consideration, of course, the question of convenience and considering merely the relative cost of gas and current. On the other hand, it is shown that in many of the smaller cities the electric light is far cheaper than gas, and electric power much cheaper than gas power. In several instances the electric light is successfully competing with petroleum. The results here shown would indicate that the Germans are just waking up to the fact that there is a profitable business to be done in small towns, as has been proved to be the case in this country when the stations are properly managed.

Of the cities tabulated, the large majority are operated on the continuous-current plan, and of these a large percentage are equipped with storage batteries. The figures show that all these stations exhibit by far the greatest economy in fuel consumption. The best result thus far obtained is that recorded of the storage battery station at Altona; namely, 0·413 kilowatt hour of current delivered to mains for one kilogram of coal; that is, close to 4lb. of coal per horse-power hour, or 5·3lb. per kilowatt hour delivered. The Table of the National Electric Light Association submitted at the last meeting showed an average of 91·7 watt hours per pound of coal, and a maximum of 208; while in the case of Altona the economy is 190 watt hours. But the point to be considered is that while the 208 watt hours per pound of coal was obtained with a station having a capacity of 8,000,000 watt hours per day, the 190 watt hours per pound of coal at Altona were obtained at a station of only 468,000 watt hours capacity per day. There is food for thought in this showing, and it ought to have some influence on future work in America.

THE EFFECT OF MECHANICAL STRESS AND OF MAGNETISATION ON THE PHYSICAL PROPERTIES OF ALLOYS OF IRON AND NICKEL AND OF MANGANESE STEEL.*

BY HERBERT TOMLINSON, F.R.S.

The author has examined the principal physical properties of three alloys of nickel with iron and of the non-magnetic manganese steel of Mr. Hadfield, together with the effects of mechanical stress and magnetisation on these properties. The three nickel-iron alloys contain 22, 25, and 30 per cent. of nickel, and are designated Specimens D, E, and F respectively; they are in the form of thin wires, and similar specimens have been previously tested by Dr. John Hopkinson for the effect of change of temperature on their magnetic properties.† Specimen F practically loses its magnetic susceptibility at a temperature below 100°C., but regains it again on cooling to the temperature of the room. Specimens D and E are magnetic in the hard-drawn condition, but become non-magnetic when heated above 600°C. They do not, however, like Specimen F, regain their magnetic susceptibility when cooled to the ordinary temperature of the room; but can be made to do so, either by the process of wire-drawing, or by cooling them a few degrees below 0°C. The density of all the specimens is diminished by wire-drawing, the simple rigidity is also diminished, and the internal molecular friction, as inferred from the logarithmic decrement of arc of torsionally oscillating wires, is considerably increased. On the contrary, whilst the specific resistance of iron, nickel, and manganese steel is increased by wire-drawing, that of the iron-nickel alloys is largely diminished. Again, whilst wire-drawing largely decreases the magnetic permeability of iron, nickel, and iron alloyed with 30 per cent. of nickel, it makes the alloys containing 22 and 25 per cent. of nickel to considerably appreciate in permeability, and, in fact, in a great measure transforms them from the almost non-magnetic to the magnetic condition. Dr. John Hopkinson has shown that a similar result can be obtained by cooling the alloys several degrees below 0°C. The magnetic properties of manganese steel cannot, however, be restored by the process of wire-drawing.

As regards the physical properties themselves, apart from the effects of stress or strain on these properties, all the nickel-iron alloys here examined have considerably less longitudinal and torsional elasticity than the pure metals nickel and iron; they also have considerably less internal friction. This last is very conspicuously the case with the alloys containing 25 per cent. nickel, which in the annealed non-magnetic condition has an internal molecular friction less than one-fourth of that of iron or nickel. For magnetising forces extending from 0·8 to 2 C.G.S. units, the alloy containing 30 per cent. of nickel is possessed of much greater magnetic permeability than iron, but for large forces the iron is superior. The other two nickel-iron alloys are, when in the annealed condition, almost as non-magnetic as Hadfield's manganese steel.

Longitudinal traction produces on both the specific resistance and the thermo-electric height of the alloys of nickel with iron, an effect which is intermediate to that produced on the pure metals nickel and iron. The magnetising forces employed ranged for the most part between 40 and 80 C.G.S. units, and the results obtained refer only to the elastic effects of the force, which effects are approximately proportional to the force itself. These elastic effects are much greater in proportion to the change of magnetic induction than are the residual effects. The change of both specific resistance and thermo-electric height produced by a C.G.S. unit of magnetic stress, is in all cases enormously greater than that produced by a C.G.S. unit of mechanical stress.

The effects of mechanical stress on the magnetic permeability of all the different iron-nickel alloys are fully exhibited in this Paper. Speaking roughly, they lie between the corresponding effects for the pure metals iron and nickel.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June* 22, 1894.

The United States Patent Office.—In the argument last week of Counsel for the Government in the suit to annul the Berliner telephone patent some severe charges were made against employés of the Patent Office, and against the administration of that important bureau. It was charged that there was collusion between the Bell Telephone Company and the Patent Office officials, or at least a tacit agreement between them, the result of which was to delay the issue of the patent fourteen years. The fact is referred to as suggestive that two examiners of the Patent Office, who left the employment of the Government to enter that of the Bell Company, have since testified eagerly to the great anxiety shown by Counsel for the defence to hasten the issue of the patent. This somewhat singular arraignment of one department of the Government by another is rendered more notable by the extreme severity of language in which the action—and non-action—of the Patent Office is referred to.

The Buffalo Cataract Construction Company.—Messrs. Houston and Kennelly have been appointed engineers to the Buffalo Cataract Construction Company. This firm has also been retained as experts by one of the two large storage battery companies of this country that are now in litigation.

CORRESPONDENCE.

CURRENT-RUSHES INTO TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the introductory portion of Mr. Hay's Paper on the above subject, which you published in last week's *Electrician*, the writer makes the remark that he is not aware of any experimental evidence for these current-rushes. As this effect was first pointed out by me in a Paper read before the Institution of Electrical Engineers in 1892, perhaps you will permit me to draw Mr. Hay's attention to the fact that about eight pages of the *Journal* of the Institution of Electrical Engineers, Vol. XXI., 1892, are occupied with a detailed account of the experimental evidence on which I based my conclusions. Mr. Mordey afterwards repeated most of the experiments and added some further observations, which he describes in his remarks on my Paper. Mr. Hay will find on investigation that the experimental evidence I adduced was very complete. Any additional observations which Mr. Hay may make will be valuable, but he will find that any theory, to be satisfactory, must take into account all the facts already accumulated. Much other information I have collected on the above subject was not referred to in my Paper, but was gathered from extensive observations of the behaviour of transformers on commercial circuits. It is, perhaps, premature to criticise a Paper not completely published; but I may mention that one of my experiments was directed to determine whether the rush was unidirectional or alternating. Mr. Hay will find that the experimental evidence is not quite in accord with his simple theory of the matter. At a very early stage of my study of these effects, I adopted, but subsequently abandoned as an explanation, the theory now proposed by Mr. Hay, as it in no way appears to explain certain well-ascertained facts on the method by which these current-rushes take place or can be invariably prevented. Mr. Hay will see that I considered very fully not only the disease, but the cure, for an effect which had sometimes very disastrous results. I have not the smallest desire to claim finality for any of my conclusions; but Mr. Hay is probably not aware that those who are interested practically in transformer systems have had abundant opportunities, and, indeed, compulsion, to investigate experimentally in the fullest possible manner a subject which he appears to think has been incompletely examined.—Yours, &c., J. A. FLEMING.

University College, London.

LEGAL INTELLIGENCE.

Re Woodhouse and Rawson United (Limited).

THURSDAY, JUNE 28TH.

After Mr. M. Dundas had been further examined, as stated last week,

Lord ABERDARE was called, and in reply to the Official Receiver stated that he was one of the original Directors of the United Company. He had a considerable interest in the Company, to the extent of something like £4,000. He had actually invested £3,600, and there was a further liability of £700. He could not say that he was consulted about the amalgamation, but he was informed of it, and was asked to become a Director. At that time he understood that the enterprise was to be wholly an industrial one. He refused for a long time to become a Director, on the ground that he could not accept such a position unless he was able to take an active part in the work, and he felt that that, as he was living in South Wales, would be impossible. Mr. Rawson, however, suggested that, as he could not attend personally at the meetings of the Board, his son-in-law, Mr. Whately, in whom he (witness) had the utmost confidence, should attend in his behalf. Upon that condition he accepted. Just about the time the Company went to allotment he fell ill (in July), and did not recover sufficiently to take any interest in the business until the end of October; he attended a meeting in December, but he was still suffering from the effects of his severe illness, and was again absent until February. In the July following he came to the conclusion that he was unable to do the work of a Director; and, whilst he had every confidence in his colleagues, and knew that his son-in-law had some influence at the Board meetings, still he had no vote, and he (witness) decided to retire. He would have retired at once, but that he feared his doing so might be misinterpreted and injury be caused to the Company; consequently he resolved to postpone his withdrawal until he had had an opportunity of meeting the shareholders, and for various reasons that did not occur until October. He was not present when the report of the auditor regarding the nature of the profits made by Woodhouse and Rawson (Limited) was produced, and it was not until a period much later that he become aware of the existence of such a report. It was explained to him that it was produced at a meeting of the Directors at a time when he was conducting an inquiry for the Government, and that it was then carefully considered; but he was not quite satisfied, because he thought it ought to have been communicated to him. He thought he must have been aware of the nature of the Woodhouse and Rawson profits before the prospectus of the United Company was issued. All these things were threshed out with extraordinary minuteness and care at the Board meetings. The Directors were men of high and unblemished character, and a solicitor was in regular attendance to advise them upon every step. That gentleman said that in the whole of his long experience he had never known Directors take so much pains to be satisfied about everything.

The OFFICIAL RECEIVER: If I put it to you that that £21,440 was principally made up of the successful flotation of the Elmore Copper Company, would that surprise you? Would it have been in your knowledge at the time?—I think it must have been in my knowledge at the time the prospectus was issued; it was not at the time I consented to become a Director.

A very large sum was paid for goodwill—£75,000, and £85,000 for patents, in addition to stock and so on. Did you look into the question of the value of those things?—I have not the slightest doubt I did. Doubts were constantly thrown by one or other of the Directors as to the trustworthiness of the valuation, and the utmost pains were taken to secure an accurate valuation. I believe that the valuations were made with perfect honesty, and the Directors were ultimately satisfied that that was so. Everything was very thoroughly gone into, and nothing was decided at but one sitting.

Did you look at Mr. Edmunds as being a thoroughly independent valuer?—I must have done so; but I cannot recollect all the circumstances that influenced me in accepting Mr. Edmunds' valuation.

Mr. Edmunds was valuing these patents at £159,000; the Managing Director tells me they were worth a much higher figure. Mr. Edmunds says he was paid £25 in cash, and was to receive £25 more if the Company went to allotment. I think that would strike you as rather an inadequate fee, would it not?—It certainly would.

If a man was going into it as a thoroughly independent man, with the view of advising a purchaser whether those patents were worth the money, it was a small fee?—It depends upon the amount of consideration necessary. I do not know what was submitted, or what amount of inquiry was necessary. I doubt whether I was consulted as to the amount of consideration. I have no doubt he would take care that he had a sufficient payment.

The REGISTRAR: If I remember aright, there were two valuations?

The OFFICIAL RECEIVER: Yes, one in 1887. But it would take the same work two years later to be properly done. (To witness) As regards the goodwill did you form an independent judgment?—All I can say is, this, like everything else, was carefully threshed out by competent men. Beyond that I cannot say.

Whose judgment did you rely on amongst the Directors?—I cannot exactly apportion that. I looked on Sir Albert Cappel and Mr. Philip Rawson, who was entirely unconnected with the promoters, as men of great experience; Sir John Coode seemed to me a man of great business faculty. I forget who the others were; but they all seemed to me men not only fully awake to their responsibilities, but also quite competent to see that what was proper was done.

Of the original Directors those three who retired, Sir John Coode, Sir Albert Cappel and Col. Howard Vincent, were entirely unconnected with

Digitized by Google

any of the Woodhouse and Rawson Companies?—They had no shares?—I cannot say. All I know is they were fully persuaded of the honesty and completeness of this valuation, and it was not on that ground that they ceased to belong to the Company. That was entirely due to what they regarded as the inadequacy of the subscription.

At the same time they said they were not quite satisfied with the way things were conducted.—Well, that could not apply to this valuation.

WITNESS, continuing, said he was not present at the meeting at which they actually resigned, and he had no knowledge of the circular sent out after their resignation. The knowledge of the existence of Mr. Pixley's report of 1889 on the accounts of 1888 must have been communicated to him by Mr. Whateley, and he wrote somewhat strongly about its not having been communicated to him and to the shareholders, and requested that a meeting should be held to discuss that matter, and also the financial position of the United Company generally. At that meeting he was informed that the report had been fully discussed, and that all the Directors, including those who had retired, were quite satisfied with the explanations given. The whole matter of the financial position of the Company was gone into at that meeting, and the result was the institution of a monthly audit.

A number of letters which passed between Lord Aberdare and Sir Rawson Rawson were here read by the Official Receiver, from which it appeared that Lord Aberdare was dissatisfied with reference to numerous points, and that, even after counsel's opinion was obtained, he was opposed to the payment of dividend out of profits obtained by the sale of land to the Kensington Stores.

The OFFICIAL RECEIVER: Was your managing director benefitted considerably by the regarding of this £17,000 as revenue?—He received 25 per cent.—Was that discussed?—I cannot say whether it was or not. But this I venture to say: No doubt Mr. Fred. Rawson had his deficiencies as a managing director, and in me he had a severe critic; but I think him a perfectly upright and honourable man.

Were you aware that on five out of six departments there was a considerable loss, and that on only one department, the Works department, was there a profit?—I knew some of them were worked at a loss. I was under the impression that they were all good, sound businesses, but that through exceptional circumstances they were not paying then.

Mr. PILLING: Had you ever it on your mind at the time of the amalgamation that you were going to get your capital in Woodhouse and Rawson (Limited) back four times over?—No.

If I say that the balance-sheet of Woodhouse and Rawson (Limited) shows those figures, would that be correct?—I suppose so, but I do not think there is any such statement.

If the figures in the books relating to the assets had worked out according to the papers put before the shareholders you do not know that your share would have been £14,000 in place of your £3,600?—No such vision ever presented itself to my mind.

Mr. MUIR MACKENZIE: I object to such a statement going upon the notes. The gentleman is putting forward a purely fabricated statement.

The REGISTRAR said Mr. Pilling was conducting his examination in a manner which was not at all discreet.

Mr. PILLING: I am going by the balance-sheet of June, 1889. There is shown a surplus of £97,800, and reckoning the amounts paid for goodwill and patent rights, there should be four times the original capital, as I have said. I do not care whether that is right or wrong.

Mr. MUIR MACKENZIE: I know you do not care whether that is true or false.

The REGISTRAR: I think Mr. Muir Mackenzie is fully justified in making that statement.

Mr. PILLING: I ask is this an open Court?

The REGISTRAR: You may ask any fair question, but you may not make statements.

The OFFICIAL RECEIVER: I think Mr. Pilling is right in the point he is trying to make. There is a surplus shown of so much, and Mr. Pilling says the assets of goodwill for which the United Company paid this large sum should be added to that surplus.

Mr. PILLING: I have not been an accountant for 20 years without knowing what figures are.

The REGISTRAR: I desire to give you every fair chance.

WITNESS, further examined by Mr. Pilling, said all he did with regard to his shares in Woodhouse and Rawson (Limited) was to transfer his interest in the United Company to an exactly equivalent amount. He had never trafficked in the shares, and never received a single penny by way of bonus, or in any other way than as dividend. He participated in no distribution of assets of the Limited Company.

Examined by Mr. H. G. Rawson, WITNESS said Sir Rawson Rawson always gave him information, in replying to his letters, to the fullest extent possible, and even in the light of later knowledge he had never had occasion to doubt the *bona fides* of the statements which he made. Sir Rawson sent him, at his request, a full analysis of the balance-sheet for the year 1889-9, and also a statement explaining the way in which the profits had been arrived at.

Some point has been made of the industrial and other operations of the business, and you have replied that when first asked to become a Director you understood the business to be purely industrial. Is it present to your mind that the sale of the Elmore patents to the Foreign Elmore Company took place on or about June 11, 1889, the date of that prospectus?—You must not confound two things. When I was asked to become a Director—it may have been my fault—it never entered into my mind that it was anything more than the amalgamation of these various companies, and it was only slowly and by degrees that it was borne in upon me that there was other business, when I found the Elmore, which seemed to me a very valuable property, in the hands of the Company. I certainly should never have dreamt of joining this Company if I had supposed it was for the purpose of promoting other companies. Beyond question that was part of the reason for my subsequent retirement; not from want of confidence in the proficiency of the Directors, but the business was new and strange to me, it took me out of my depth, and I did not like it.

Am I right in stating that the only salary of the Managing Director was his commission?—I think so.

Did you do your utmost as a prominent member of the Board to hold even the scales as between his interests on the one hand and those of the shareholders on the other?—I am sure I must have done so, but I cannot give any particular case.

Would not such a case be when you were endeavouring to carry to reserve sums of money which counsel had the opinion should be divided. It was a question between justice to your Managing Director and considerations of prudence?—I may say that was not in my mind. I was merely considering what was fairly divisible and what was not divisible.

The REGISTRAR: How were you introduced to the Company?—I knew Mr. Rawson's family, and was very much interested in these electrical works, and consequently I invested some money in the works, which I thought among the best of the day. On this interest Mr. Rawson, thinking, no doubt, that my name and my work as a Director might be of use, asked me to join. As I have said, I refused over and over again at first: then came the offer of my being represented by Mr. Whateley, and I accepted.

Examined by Mr. Muir Mackenzie: Mr. Whateley held 789 Ordinary shares in the Company, and 351 Preference shares. They were in constant correspondence respecting the affairs of the Company.

Mr. A. HOSTER, one of the liquidators of Woodhouse and Rawson (Limited), in reply to the Official Receiver, said a certain proportion of the shares he had held in that Company really belonged to Mr. F. L. Rawson. He was unable to say precisely what he as liquidator was able to get from the Manufacturing and Supply Companies as representing the debts of those Companies to the Limited Company; he got all there was. The shares in those Companies were to a great extent taken over by the Limited Company. He could not say whether they ever realised more than 10s. in the £ in respect of those debts. All the rights and interests of the Company in the Automatic Machines Company were sold to Mr. F. L. Rawson for 1s., and that sum was expended in stamps for use in the liquidation. But it was not fair to let that statement go by itself without an explanation. The stock and everything that was valuable in the Automatic Machines Company was in the hands of a receiver on behalf of the debenture holders, but in order to close the liquidation of the Limited Company it was necessary to dispose of the rights of that Company, although they were not worth anything, and Mr. F. L. Rawson offered 1s. merely to facilitate the liquidation. He promised, however, to pay over anything which he might realise in excess of the 1s. There were arbitration proceedings going on between them and the Automatic Company, and the officials of the latter were acting scandalously in his opinion in allowing the stock to lie idle and spoiling. He himself had a claim of several thousand pounds against the Limited Company, but that did not appear in the accounts or in Mr. Pixley's report of June, 1890. It was only ascertained through the liquidation two years later. He received a very small amount in cash, and practically the whole in shares of the United Company and the Schulke Gas Company.

By Mr. F. L. Rawson: In the beginning of 1889 he had charge of the negotiations for the sale of the Foreign Elmore patents in Paris. He sold those patents for £700,000, and the contract was signed; but difficulties arose, and it was never carried out. All the debts of the manufacturing Company were collected and handed over to the Limited Company. The United Company refused to have anything to do with the lamp business until the legal difficulties were cleared up; and, in consequence, the Limited, Manufacturing, and Supply Companies were put to considerable expense. If the arrangement made in the middle of 1889 as regards the British licence had been carried out it would have been of immense value. He should say an output of 50,000 lamps would have been a small amount by this time; the profit on each lamp, at the old price, would have been between 1s. 6d. and 2s. So far as the filament was concerned, the Woodhouse and Rawson lamp was the best he knew. He had even had complaints that it lasted too long. He had had considerable experience as a lamp manufacturer in France. He did not recollect Mr. Rawson complaining at meetings of the Limited Company that the subsidiary Companies were sacrificed for the Limited Company; but there were a good many observations of a similar kind made. When the Limited Company was formed a guarantee from Messrs. Woodhouse and Rawson was insisted upon; by subsequent arrangements that guarantee was changed from time to time; but still they had a substantial guarantee. He conducted the negotiations between the British Electric Light Company and Woodhouse and Rawson (Limited). In 1891 they anticipated making a large number of lamps under that agreement, which was signed and approved by the Chairman of the British Electric Light Company. Then when the subsidiary Companies entered upon liquidation they went back upon their agreement and consequently those large profits were lost. The licence was granted to the British Company in 1831 by Edison and Swan at a 10 per cent. royalty. The Edison-Swan Company refused to allow the Woodhouse and Rawson Manufacturing Company to manufacture the lamps on a royalty of 1s. 6d. per lamp. Then they (Woodhouse and Rawson) found that this licence had been granted to the British Company, and they resuscitated it: and an arrangement was made whereby the United Company was to manufacture for the British Company, and the British would sell to the public, the profits to be divided between the two companies. Mr. Vernon Harcourt had reported that the Schulke gas lamp was the best ever made. He (Mr. Rawson) wanted the Schulke Company to amalgamate with the Welsbach, and the Schulke refused. Such an amalgamation would have been very valuable. Mr. Rawson was Chairman of the Welsbach Investigation Committee, and made the offer on behalf of that Company. The Welsbach Company had this year made a profit of £25,000.

Digitized by Google

By Mr. Jenkins: The arbitration with regard to the Automatic Company took up the greater part of three years, and the result was that the arbitrator's award was in Woodhouse and Rawson's favour. A receiver was put in for the debenture-holders, and he personally objected to the Woodhouse and Rawson taking up the arbitrator's award, as there were expenses to the amount of £700.

By Mr. H. G. Rawson: The Automatic Company complained that the machines were not properly made, and that they could not use them. As a matter of fact, they never tried, and £70,000 worth of machinery was improperly stored and allowed practically to fall to pieces, when they might have been earning large profits. When the Company commenced operations the earnings were sufficient to pay for a box in one week. He was aware that under the estimate he had made of an output of 50,000 lamps the profits would amount to £250,000 a year. He carried to a conclusion the agreement between the British Company and the Edison-Swan Company, and had gone carefully into the probable profits to be earned under those patents.

By the Registrar: As much as 100 and even 200 guineas were sometimes paid for valuations of patents; but the fee depended upon the amount of inquiry and consideration necessary, and upon the importance of the patents.

Mr. F. L. RAWSON: The Directors chose Mr. Edmunds. He had valued the patents before, and could do it quickly.

Mr. EVE said he would respectfully ask, through the Registrar, that the Official Receiver would do all he could to shorten the examination. He had so far put a lot of gentlemen into the box who knew very little about the affairs of the Company. If he really wished to get at the facts he would have called the Managing Director at once. He would ask the Registrar to say that Mr. F. L. Rawson must now be called.

The REGISTRAR said he did not think he should interfere with the Official Receiver's discretion as to the witnesses he should call.

Mr. EVE said it was an injustice to his clients to be kept there day after day unnecessarily.

Mr. JENKINS supported Mr. Eve's protest, and repeated that if Mr. Stewart wanted the facts he would call Mr. Rawson.

The REGISTRAR said Mr. Stewart would probably consider the matter by the time of the next sitting.

THURSDAY, JULY 5TH.

The OFFICIAL RECEIVER said, whilst desiring as far as possible to shorten the proceedings, he could not see his way to acceding to Mr. Eve's request by examining Mr. F. L. Rawson next.

Mr. T. H. LAMBERT, a Director of Woodhouse and Rawson (Limited), and one of the liquidators, agreed with the statement of Mr. Hoster that no cash was realised upon account of the shares held by the Company in the subsidiary companies. He was under the impression that the valuer of the patents was appointed by the Directors of the Limited Company, or by Mr. Hoster and Mr. F. L. Rawson on behalf of the Board.

By Mr. Pilling: When the Limited Company took over the partnership of Messrs. Woodhouse and Rawson, there were certain book debts against which a guarantee was given by the partners. The book debts were never paid, and there was some arrangement with regard to the guarantee, but he did not recollect how it was wiped out. £10,000 remuneration was voted to Mr. F. L. Rawson by the Limited Company for his services in promoting several companies, but he did not think that had any reference to the promotion of the United Company.

By Mr. F. L. Rawson: He regarded the manufacturing business as likely to become a very profitable business. Mr. F. L. Rawson usually took the part of the United Company, and Mr. Hoster that of the Limited Company in the negotiations, and there were frequent disagreements between those two gentlemen, because Mr. Hoster said Mr. Rawson wanted too much for the United Company. Mr. Hoster had also said in his presence that Mr. Rawson was not acting fairly to his family or to himself by sacrificing himself in the interests of the shareholders of the United Company.

Mr. PHILIP RAWSON, the next witness, said he was not related to Mr. Frederick Rawson or his father in any way; but as far back as 1885 he lent the firm of Woodhouse and Rawson £2,000, and that was his first connection with the Company. He was to have the option of taking shares, and he afterwards did take shares. He eventually put another £2,000 into the business. He had never sold a share. He became a Director of the Manufacturing Company, and subsequently of the United Company. He had had a serious illness, and his recollection of what took place at the time of the formation of the United Company was very defective. He regarded the circular sent out upon the withdrawal of three of the original Directors, although he did not recollect having seen it before, as a quite sufficient intimation that applicants might withdraw their applications for shares, although it did not specifically say so. He did not think that Baron Albert Grant was consulted by Mr. F. L. Rawson with regard to the formation of the United Company. There was a minute showing that the Managing Director was to be instructed that any relations with the Phœnix Trust, or with any financial adviser other than those which might be approved by the Board, should cease with all convenient speed. He remembered that resolution being passed, but was not aware that Baron Grant was connected with the Phœnix Trust. He supposed he must have known that a circular was sent out, puffing the Elmore shares after they had been sold to the Phœnix Trust; but he had no recollection. It had escaped his memory that Mr. F. L. Rawson and himself were appointed a finance committee, and he did not recollect attending a meeting of such committee. He did not think the extension of the financial accounts to thirteen months, whilst the industrial accounts were made up for eleven months in 1891, was done for the purpose of including the supposed profit on the formation of the Epstein Company. He eventually resigned on account of ill-health.

Sir LEOPOLD M'CLINTOCK stated that he was asked to become a Director of the United Company in place of one of the gentlemen who resigned, and he consented; but soon found that he had too many other duties to permit of his giving close attention to the business, and also that the financial part of the business was taking him out of his depth. He wished to resign in August, but was induced to remain a little longer as a matter of courtesy. He had no mistrust of any kind, and did not doubt the accuracy of any of the statements made to him respecting the Company's affairs; he did not make any thorough investigation, as he regarded it as a going concern.

Mr. A. L. FOLEY, for some time secretary, was examined, but gave no material evidence.

Mr. W. T. STUTCHBURY, who became secretary in 1891, and afterwards manager, said within two or three months of his joining the Company he told Sir Rawson Rawson he thought they were making a mistake in not trying to develop the resources of the Company. Sir Rawson admitted that perhaps it had been neglected; but at the same time the Directors looked for the greater part of the profit to the development of the financial side of the business, and he agreed with his son that where they had brought out one Company they would bring out ten, not with so much profit, probably, but still with a fair margin in each case.

The further examination was adjourned until to-morrow (Friday).

Winnipeg Street Railway Company v. Winnipeg Electric Street Railway Company and the City of Winnipeg.

Before the Judicial Committee of the Privy Council last week an appeal from a judgment of the Court of Queen's Bench in Manitoba was heard.

The case was recently argued before a Board consisting of the Lord Chancellor, Lord Watson, Lord Macnaghten, and Sir Richard Couch, when judgment was reserved, and

Lord WATSON, in now delivering judgment, went fully into the question at issue between the parties. The action was originally brought to secure certain rights claimed by the appellant Company under a deed of indenture executed in July, 1882, between the appellants and the authorities of the city of Winnipeg for the construction and working of street railways within that city. Having very exhaustively reviewed the evidence, his Lordship said that the privileges conceded to the appellant Company were to endure for 25 years from the date of the deed of indenture executed in July, 1882, it being in the option of the city to acquire the Company's undertaking at the expiry of that period upon their giving five years' previous notice to that effect. The Company at once proceeded with their tramway enterprise, in accordance with the terms of the said deed, which gave the appellant Company powers to use and occupy such parts of the streets of the city as were necessary for the use and working of their railways. Before 1892 they had completed and were in course of working upwards of nine miles of street railways. In February, 1892, the Mayor and Council of Winnipeg passed a bye-law authorising James Ross and William M'Kenzie to construct railways upon the streets of the city. The respondent Company in April, 1892, obtained an Act of the Provincial Legislature, incorporating them for the purpose of their taking over the rights acquired by Ross and M'Kenzie, and carrying out the scheme sanctioned by the bye-law of February. The respondent Company's Bill was opposed by the appellant Company, who alleged that they were entitled to a monopoly for the period of 25 years from the date of their agreement of all those streets in which their railways had already been opened for traffic, and also of certain other streets in which they had intimated that they were willing and ready to construct and operate railways. This right was (the appellants contended) specifically safeguarded by a clause in the Company's Act. It was (said his Lordship) unnecessary to criticise the enactments of this clause, because it was not disputed that these would be sufficient to protect any such privilege as that which was claimed by the appellant Company in the appeal. The appellants commenced the present suit by presenting to the Court of Queen's Bench a bill of complaint against the respondent Company and also against the city of Winnipeg. The appellants craved a declaration of the exclusive rights which they claimed against both respondents, and an injunction restraining the respondent Company from constructing or operating railways in any street occupied by the appellants, or in any street not then occupied by them until an offer had been made to them of the privilege of constructing a railway upon it and had not been accepted by them within two months. In defence to the suit the respondents maintained, in the first place, that the appellant Company were not possessed of any exclusive privilege, and that the city had therefore power to sanction the construction of railways by the respondent Company, in any street of the city, whether it was already occupied by the Company or not; and, in the second place, that, if the city had in fact agreed to give the appellant Company a monopoly of the railway traffic in certain streets, the agreement was *ultra vires* and void. The original action had been decided against the appellants, as had also an appeal before a full Court. In the full Court both points were decided against the appellants. Their Lordships did not find a single expression tending to show that the Legislature either intended that no tramways other than those of the appellant Company were to occupy the streets of Winnipeg or had it in contemplation that the appellants were to obtain a monopoly from the Council of the city. If such a claim were valid, the right must be derived from the indenture of 1882; but the only authority there given was expressly limited to the construction, maintenance, and operation in each street which the Company might select for that purpose, of a railway consisting of a single or double line of rails, with needful appurtenances; "and such railway shall have the exclusive right of such portion of any street or streets as shall be occupied by the said railway, and shall be worked under such regulations as may be necessary for the protection of the citizens of said city." The appellant Company argued that the

Digitized by Google

words last quoted ought to be construed as a declaration that the Company's railway was to be the only railway permitted to occupy any part of those streets into which it might be introduced by them. In their Lordships' opinion, any such construction would be contrary to the plain meaning of the words of the agreement, which in substance implied that the Company were to have no use or occupation of, and no concern with, those portions of any street which were not actually occupied by their double or single line of rails. The only clause at all bearing out the appellant's contention ran thus:—"In the event of any other parties proposing to construct street railways on any of the streets not occupied by the parties to whom the privilege is now to be granted, the nature of the proposal thus made shall be communicated to them, and the option of constructing such proposed railway on similar conditions as are herein stipulated shall be offered; but if such preference is not accepted within two months, then the Corporation may grant the privilege to any other parties." Their Lordships did not think that it was going too far to say that, laying aside the terms of that stipulation, there was not a single expression in the deed of agreement which gave the least countenance to the suggestion that the Municipal Council intended to grant to the appellants an exclusive right to use and occupy any street for railway purposes. Those clauses of the deed which dealt directly with the use and occupation of the streets which were to be enjoyed by the Company were not only silent upon the question of exclusive right, but were conceived in terms which it was exceedingly difficult to reconcile with the theory of an intention to create such a right. Had there been any such intention, nothing would have been easier than to indicate its existence, in the proper place, either expressly or by implication. Their Lordships were therefore of opinion that the leading clauses of the agreement which defined the Company's rights of user and occupation, could not be qualified by a subsidiary clause, such as that upon which the appellant Company relied, unless its terms were clear and coercive. They were unable to hold that the terms of the clause in question were in themselves sufficient to control the plain meaning of the previous stipulations and to constitute the right of monopoly which the appellant company claimed. The clause could not imply an undertaking on the part of the council that in the event of a rival company obtaining statutory powers, and desiring to compete with the appellant Company in those streets in which their system had already been established, the Council should be bound, although against the interest of the community which it represented, to refuse its assent to the new scheme and to allow the Company to remain in the enjoyment of a monopoly. Their Lordships' decision, therefore, was that the judgments appealed from ought to be affirmed, and the appellant Company must pay one set of costs to the respondents.

Brasyer v. Harness and Another.

This action came on for hearing on Tuesday before Mr. Justice Charles and a Special Jury in Queen's Bench Court III. In this action Colonel Jeremiah Brasyer, the plaintiff, sued the defendant, Cornelius Bennett Harness, the manager of the Medical Battery Company, and James Montgomery M'Cully, a surgeon, to recover damages for alleged negligence and fradulent misrepresentation in connection with their advertised cures by electrical process. The defendant Harness denied the alleged misrepresentations and also that the plaintiff had been induced to pay the £52. 10s. he had paid by any such misrepresentations. He further denied that the applications and methods adopted by him for the cure of the plaintiff were to his knowledge valueless. This defendant counter-claimed for damages in respect of a malicious prosecution, which the plaintiff had commenced against him in November, 1893, and which was dismissed on January 31, 1894, after numerous remands. The defendant, J. M. M'Cully, in a separate defence, denied all the allegations of fraudulent misrepresentation, and also that he had, by his negligent treatment of the plaintiff, injured the plaintiff's arm as alleged. He also counter-claimed for damages for malicious prosecution. The plaintiff joined issue upon both the defences, and pleaded to the counter-claim that in prosecuting the defendants he had acted without malice, and that there was no absence of reasonable and probable cause. Mr. Witt, Q.C., Mr. T. Terrell, and Mr. H. C. Gollan were for the plaintiff; Mr. Jelf, Q C., and Mr. H. Avory were for the defendant Harness; and Mr. Abinger and Mr. W. Campbell appeared for the defendant M'Cully.

The hearing of this case was resumed on Wednesday. Mr. HARNESS, cross-examined by Mr. Witt, Q.C., said that in 1872 he stated a wholesale business on his own account. In 1870 he became bankrupt. After obtaining his discharge he was connected with the Xylonite Company up to 1880. In 1880 he went in for electricity. Up to 1885, when the Electrical Battery Company was established, he never studied medicine, electricity, anatomy, or anything of that kind. The various books published in connection with his business had been written by competent gentlemen. He believed that the electric treatment would cure various diseases, but did not personally himself pretend to cure these diseases. His Company had, it was true, gone back to the "connected" type of belt, but that was against his own opinion. Referring to the various libel actions, Mr. Harness stated generally that his reasons for either compromising them or not continuing them was the fact that he was a ruined man. He had no doubt made mistakes, but maintained most emphatically that all the gross charges, insinuations, and accusations in articles published against him were absolutely false.

Re-examined by Mr. Jelf, Q.C., WITNESS stated that the statements in the various libels as to the profits made on the sale of belts were absolutely false. The expenditure of £200,000 in five years in advertising was necessary, and not at all too high or unusual for the legitimate purposes of such a business.

M. LOREAU (called and examined by Mr. Avory) said he was acquainted with electro-therapeutics, and had worked under the well-known Dr. Charcot. In June, 1888, he was introduced to Mr. Harness, and came after and assisted him to manage his Oxford-street establishment, where he remained until March, 1892, at a salary of £400 a year. During that period he introduced a number of novelties in electrical appliances, such as were found in use at the Salpêtrière. He had visited the various London hospitals, and did not consider their electric equipments so complete as that of Mr. Harness's establishment. As an expert it was his opinion that the belts without any connection were electrical appliances. He remembered Dr. Vigoroux being appointed as consulting medical adviser to Mr. Harness.

At this stage the hearing was adjourned until Thursday.

On the hearing of this action being resumed yesterday, Mr. S. J. MACKAY, formerly science correspondent of the *Standard*, said he had experimented with one of the Harness belts. He had worn one for nine months. He did not form any permanent opinion of the belt.

Cross-examined by Mr. WITT: Did an article or report, purporting to be from your pen, on Harness's establishment appear in the *Standard*?—I think not.

Was there not an article in the *Standard* on Harness's establishment?—I do not remember it.

Was it in the *Westminster Gazette*?—It might be.

Did it purport to be signed by you?—It did.

Did the same article, or substantially the same, appear in the *St. James's Gazette*?—It appeared in several papers; whether in the *St. James's Gazette* or not I do not know.

Purporting to be signed by you?—I said purporting to be signed by me.

Was it signed by you?—No.

How did it get into the paper with your signature?—I really don't know.

Cannot you help me?—Witness hereupon related the story of how he had gone away from London, and on his return in July purchased a paper, and was astounded to see the article and his signature attached. He saw the editor, who showed him the manuscript and his signature to it, which was his in appearance. He supposed they had got hold of his signature at Harness's establishment. It was an electrotyped signature, and it was a good imitation of his. Witness never gave authority to Harness or anybody else to put his signature to the article. In the main, it contained opinions expressed in a report in course of preparation. The more florid part of it was inspired by Harness. The interlineations sprang from Harness's editorial department.

Mr. WITT: Did your resign your position on the *Standard* in consequence of the matter?

WITNESS: The tension between me and the *Standard* became so strained that I thought it incumbent upon me to resign.

A considerable volume of expert electrical evidence followed.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1894 Edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK IS NOW READY. This valuable book contains 1,000 closely-printed pages, and several new and useful features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," being four Lectures delivered before the Royal Institution in April-May, 1894, by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is in preparation, and will shortly be published.

"ELECTROMAGNETIC THEORY," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—This book, written by Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"INVENTIONS, RESEARCHES AND WRITINGS OF NIKOLA TESLA," by T. Commerford Martin, may be obtained from the Publisher of *The Electrician*, and a copy will be forwarded post free on receipt of 16s. 6d.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

TENDERS INVITED.—The London County Council invite tenders for the construction of the generating station buildings in connection with the electric light installation for the Victoria Embankment and Westminster and Waterloo Bridges. Specifications, &c., can be obtained at the Engineers' Department, County Hall, Spring Gardens, London, S.W., and tenders must be sent in to Mr. H. de la Hooke, Clerk to the Council, before 10 o'clock Tuesday, the 10th inst.

——— The Southport Corporation invite tenders for electric wires, switchings, fittings, &c., required in the lighting of the Town Hall and Cambridge Hall at Southport. Further particulars will be found in our advertisement columns, and copies of the specification and other particulars may be obtained of the Town Clerk, Mr. J. Davies Williams, Town Hall, Southport.

Digitized by Google

Tenders Invited.—Tenders are invited for a suitable plant for lighting a foundry and engineering works. Apply, Stewart; Blackwood, Mon.

——— The Wolverhampton Corporation require tenders for wiring and the erection of selected fittings for the lighting of the Town Hall, Art Gallery, School of Art, Free Library, and Market Hall. Particulars can be obtained of the Borough Electrical Engineer. The same Corporation also invite tenders for the supply of electric fittings suitable for the above installation.

Tenders Accepted.—The following tenders have been received by the Bedford Corporation for buildings, machinery, and plant required in connection with the electric lighting scheme :—

	£	s.	d.
Mains and Transformers.			
Pritchetts and Gold	3,465	10	0
Porter and Harrison	3,350	0	0
New and Mayne	3,282	2	6
Brush Electrical Engineering Company	3,C68	0	0
Electric Construction Company	2,780	0	0
British Insulated Wire Company	2,686	10	5
India Rubber, Gutta Percha, and Telegraph Works Company	2,598	0	0
J. Fowler and Co.	2,560	0	0
W. T. Glover and Co.	2,520	15	0
Henley's Telegraph Works	2,463	16	8
Hooper's Telegraph and India-rubber Works	2,450	0	0
Johnson and Phillips	2,416	4	0
Crompton and Co.	2,333	0	0
Telegraph Manufacturing Company, Helsby (accepted)	2,271	5	2
Siemens Bros. and Co. (incomplete tender)	2,215	0	0
Plant.			
Baily, Grundy and Barrett	9,320	0	0
Siemens Bros. and Co.	6,290	0	0
J. Fowler and Co. (Leeds)	6,123	0	0
Brush Electrical Manufacturing Company	5,890	0	0
Crompton and Co.	5,791	0	0
Allen, Son and Co.	5,731	0	0
Electric Construction Company	5,317	0	0
Johnson and Phillips, London (accepted)	4,888	0	0
Travelling Crane.			
Bedford Engineering Company	120	0	0
Messrs. Grafton and Co., Bedford (accepted)	85	0	0
Buildings and Shaft.			
G. E. Fathers	2,022	13	6
J. J. Potter	1,911	0	0
T. H. Coleman, Bedford (accepted)	1,565	0	0

Tenders Accepted.—The Worcester Corporation have accepted the tender of the New British Electric Installation Contractors (Limited) for wiring and fitting up the Guildhall Police Station and chief constable's house, and the house in the station yard, in accordance with the specifications prepared by Mr. Preece. The wiring tender is £556. 2s. 6d., and fittings £243. 9s. 1d. The same Company's tender has been accepted for wiring the public hall, small hall, &c., at £177. 19s. 2d., and the tender of Messrs. Verity and Sons for the fittings in these latter buildings at £154. 1s. 4d.

——— The Cheltenham Corporation have accepted the tender of Messrs. Malvern for the erection of the central electric lighting station, at a cost of £1,790 ; and the tender of the Callender Company has been accepted for the supply of cables for £1,031. 8s. 4d. (subject to the high-pressure mains being guaranteed for 10 years).

Vacant Appointments.—The Technical Education Board of the London County Council is prepared to receive applications for the appointments of Inspector of Science Schools and Classes, and Inspector of Art Schools and Classes. The stipend is at the rate of £400 per annum for each appointment. Further particulars are given in our advertisement columns. Applications must be made on or before the 21st inst., on forms to be obtained of Prof. Wm. Garnett, Secretary of the Technical Education Board, 13, Spring-gardens, London, S.W.

——— The Staffordshire Technical Instruction Committee require a lecturer in metallurgy at a salary of £250 per annum. Particulars can be obtained of Mr. T. Turner, Director of Technical Instruction, County Offices, Stafford ; and applications must be in by July 14th.

——— The Corporation of Wolverhampton require a working foreman engineer for their electric works at a commencing salary of £2 per week. Applications have to be sent in by noon on July 14th.

——— The Battersea Polytechnic Institute have a vacancy for an assistant lecturer in mathematics and physics. Particulars can be obtained of Mr. J. Harwood, secretary.

New Firm.—Mr. G. E. Piggott, who was for some years with Mr. R. Applegarth, has started business at 110, Cannon-street, E.C., under the style of Piggott and Co.

Dissolutions of Partnership.—The firm of Burbey, Williamson, and Joseph, electrical engineers, of Queen Victoria-street, has been dissolved so far as regards Mr. W. S. Burbey. The business will be carried on by Messrs. Williamson and Joseph.

——— Mr. Herbert Nalder has retired from the firm of Nalder Bros. and Co., of 16, Red Lion-street, Clerkenwell. The business will be continued under the same style by Messrs. F. H. Nalder, C. W. S. Crawley, and Alfred Soames.

Warning.—Several cases have occurred recently in which goods have been obtained by a person who passes as representative of well-known electrical firms, but who possesses no authority. Messrs. Edmundsons (Limited), of Great George-street, S.W., inform us that they have had several such cases brought to their notice, and desire us to warn firms not to supply goods without their official order.

Edison and Swan United Electric Light Company.—Owing to the great increase of business the City show-room and warehouse premises of this Company in Cannon-street are altogether too small for immediate requirements, and it has been decided to erect entirely new premises at 36 and 37, Queen-street, Cheapside, where the head office, warehouses, and City show-rooms will, early in August, be removed. It is doubtless the success which has attended the opening of the Cannon-street show-rooms that has now necessitated the erection of specially-arranged premises of sufficient magnitude to meet the immediate and growing wants of the Company's business. The new premises, which will be well situated in the very centre of the City, are to be called "Ediswan Buildings."

Messrs. Swinburne and Co.'s Supplementary Catalogue.—We have received a list in which motor-alternators, dynamos, switch-board instruments, transformers, reducers for arc lamps, choking coils, and high-tension switches are illustrated and described. A new insulating flux for soldering is offered. It is claimed that it is a perfect insulator, is waterproof, non-corrosive, and improves the insulation of cotton or silk, and, unlike rosin, which merely keeps the metal clean, it is said to be a real flux. It is called "Scalpa."

Messrs. Baxendale and Co.—This firm send us lengthy particulars of installation work recently completed, including the telephonic work required at the Denbigh Lunatic Asylum, the electric lighting work at the North Pier, Blackpool, for which concentric wiring has been adopted, the cables being supplied by the British Insulated Wire Company, of Prescot, and the arc lamps are of the Brockie-Pell standard type, attached to ornamental standards. The list also contains a number of telephonic and electric lighting installations carried out by the firm in the Manchester and Oldham districts.

English-made Telephones.—The Consolidated Telephone Construction and Maintenance Company (Limited), of Farringdon-road, E.C., send us their new circular, illustrating the latest make of Gower-Bell telephones, the new Post Office telephone, and the new form of transmitter now supplied by the Company, of which they are the original manufacturers.

Messrs. J. P. Hall and Co.—We have received from this firm their new price list of dynamos and combined engine and dynamo sets, which is fully illustrated and well arranged.

Manganese.—It is stated that immense quantities of manganese have been discovered in the Caucasus Mountains between the Black and Caspian Seas, and European capitalists affirm that they will be able to deliver manganese into Baltimore, U.S.A., at $9 per ton.

Canadian Customs Dues.—Under the new Canadian Tariff Law, which took effect from March 27th last, alterations are made in the customs dues on the following articles :—For insulators of all kinds, arc and incandescent lamps, side and head lights, gas and electric light shades and globes, the duty is now 30 per cent. *ad valorem* ; copper wire, 15 per cent. *ad val.* ; wire covered with cotton, linen, silk, or other material, 30 per cent. *ad val.* ; brass wire, 10 per cent. *ad val.* ; galvanised iron wire, 25 per cent. *ad val.* ; telephone and telegraph instruments, telephone, telegraph, and electric light cables, electric and galvanic batteries, electric motors, generators, dynamos, and electrical apparatus generally, 25 per cent. *ad val.* ; electric light carbons or carbon points not exceeding 12in. in length $2·50 per thousand, and proportionately for greater or less lengths. Considerable alterations are also made in the duties on metals, engines, tubes and tubing, castings, and acids. A full list of these alterations will be found in the *Board of Trade Journal* for June and July.

Commercial Education.—The fifth examination for junior commercial certificates in connection with the London Chamber of Commerce, under its commercial education scheme, has been held during the present week. The proceedings started at King's College on Monday with the examination in practical chemistry ; and other examinations include book-keeping, writing and arithmetic, proficiency in modern languages, mathematics, mechanics and hydrostatics, electricity and magnetism, sound, light and heat,

Digitized by Google

natural history, shorthand, and drawing, for which various prizes, ranging from £20 to £2, are given to candidates under 17 years of age at the date of the commencement of the examination. The Chamber of Commerce undertakes to find employment for all candidates succeeding in gaining a certificate. Only one reward can be obtained by any candidate.

Telegraphic Addresses.—Mr. Sell has just issued the June Supplement to his "Directory of Registered Telegraphic Addresses," which contains some thousands of new registrations, cancellations, and other alterations effected during the quarter. The Supplement is sent free to all subscribers; and firms who have purchased the Directory through local booksellers or otherwise than direct from the publishing offices, are requested to send their names and addresses.

Catalogue.—We have received a copy of Messrs. J. Davis and Son's new section "B" catalogue, specially devoted to electrical plant for transmission of power, including pumping, hauling, coal cutting, drilling, &c.; electric lighting; special electric light fittings for out-door and damp and exposed situations; electric blasting apparatus, and electric signals for collieries.

"Annuaire de l'Électricité," 1894.—This Directory, published by M. Camille Rousset, 114, Rue et Place la Fayette, Paris, is just issued, and includes a list of the members of the British Institution of Electrical Engineers corrected up to January, 1893, together with a variety of lists, home and foreign.

"Gas, Water, and Electric Lighting Companies' Directory."—This useful annual, which in addition to a carefully-compiled Directory of gas and water works contains a mass of gas and waterworks statistics, is just issued by Messrs. Hazell, Watson and Viney, of Creed-lane, London, E.C. This is the eighteenth issue, and the book is revised up to March 31st last. In addition to the statistics referred to, a careful summary is made of the principal events of the previous year of interest to all concerned in the gas and water industries, as well as to many engaged in the electrical trades. The price of the book is 10s., bound in strong cloth.

Electrical Stores.—We have received a copy of the July price sheet of electrical stores and apparatus issued by the Electrical Plant and Sundries Company, of 10, Laurence Pountney-lane, E.C. A large quantity of material is included in the list.

Asylum Lighting.—The Cheshire County Council have decided to make extensive additions to the Upton Lunatic Asylum from plans prepared by Messrs. Grason and Ould. The additions are intended to accommodate 416 additional patients, and will cost £76,200, the allowance made for the electric lighting of the new building being £2,000.

Athletic Sports.—The Arc Works Athletic Club, composed of the members of Messrs. Crompton's works at Chelmsford, held their fifth annual bicycle and athletic races on Saturday last. The Company included Mr. R. E. Crompton, Miss Crompton, Mr. J. F. Albright, Mr. F. R. Reeves, and many others well known in electrical circles. Mr. W. Woodward, who was first prize winner in the one-mile flat championship last year, again proved victorious, and retained the silver challenge cup presented by Messrs. Crompton and Albright. The various events were well contested, and at the conclusion Miss Crompton distributed the prizes.

Baslow and Burnell (Derbyshire).—The Local Board decided some time back to postpone the consideration of an electric lighting scheme for the district until the new Parish Council was formed. At the last meeting correspondence was read in reference to the scheme, and an offer was received for advancing the necessary money at 3½ per cent.

Bedford.—The list of tenders received by the Bedford Corporation will be found in a previous column. At a meeting of the Corporation, at which the tenders were considered and accepted, Mr. Blaydes, the Chairman of the Electric Lighting Committee, explained that the Committee considered it essential that no time should be lost in selecting and accepting tenders for the electric lighting work, and they had therefore recommended the acceptance of tenders as indicated in the list. It was originally recommended to accepted the tender of Messrs. Siemens Bros. and Co. for mains and transformers; but upon going through the tender the Committee found that the price per yard, multiplied by the number of yards, would give a total in excess of the amount of the tender, and, as the next tender (that of the Telegraph Manufacturing Company, Limited) was only £56 more than the original tender of Messrs. Siemens Bros. and Co., the Committee recommended its acceptance. The Mayor, before taking the vote, asked Mr. Medhurst, the Corporation's Consulting Engineer, whether he considered the Telegraph Manufacturing Company a reliable firm and one upon which the Council could thoroughly rely to carry out the work, to which Mr. Medhurst replied that he was quite satisfied that the Company, who had carried out large contracts, would do the work to the Corporation's satisfaction. He had used a great deal of the cable manufactured by the Company, and had always found it up to specification. Some other slight modifications of the original tenders having been explained, the offers of Messrs. Johnson and Phillips for the plant, and of Mr. Coleman and Messrs. Grafton for the buildings and shaft and travelling crane were accepted. Mr. Blaydes then moved that it be an instruction to the Electric Lighting Committee to carry out the work of the electric lighting scheme, subject to the approval of the Local Government Board and the Board of Trade. An inquiry was to be held to empower the Corporation to borrow £12,000 to carry out the work, and he hoped there would now be no hitch to prevent their proceeding rapidly with the work.

Belfast.—Mr. M'Cowen, the resident engineer, has submitted to the Electric Lighting Committee of the Corporation a report of the progress of the electric lighting works since the Committee's last meeting. Mr. M'Cowen reports that a large number of persons outside the prescribed area have applied for the electric light.——The Young Men's Christian Association have decided to erect a large block of buildings, from the designs of Messrs. Young and Mackenzie, at a cost of £12,000, the whole of the buildings to be lighted by electricity.

Bolton.—At the meeting of the Town Council on Wednesday Alderman Myles stated that the electric lighting works, which had cost the Corporation nearly £40,000, were approaching completion, and in a few weeks the Corporation would, he hoped, be in a position to supply electric current to intending consumers.

Bournemouth.—Permission has been given to the Brush Company to fit three or four of the existing street lamps with glow lamps of various candle-powers, to be supplied with current from the transformer station near the Bournemouth Arcade. An experiment is to be made with low-tension current, and is intended for inspection by the Winchester Town Council, with whom the Brush Company are negotiating for lighting that city.

Boscombe.—The Bournemouth Electric Light Company are making extensions into this district which, when completed, will reach to the junction of Christchurch-road with the Ashley-road.

Bradford.—The Bradford Bowling Club have now lighted their bowling greens by electricity. Four 3,000-c.p. arcs are used. The lamps are provided with reflectors, and all parts of the green are by this means well lighted, enabling play to be carried on to a late hour.

Brechin.—At the annual meeting of the local gas company amongst the subjects discussed was the advisability of the Company supplying electric light within the district, with special reference to the application to Parliament by the Aberdeen Gas Company for a Provisional Order to supply electric current within the town of Brechin. No decision on the matter was arrived at.

Burton-on-Trent.—A grant of £100 has been voted to Mr. Ramsden, the Corporation's gas manager, for his services in designing and constructing the electric lighting works, and it is proposed to make him manager of the latter at a salary of £50 per annum, dating from February last.

Canterbury.—A public meeting was held at the Guildhall, Canterbury, last week, to consider the proposals of the County of London and Brush Provincial Electric Lighting Company, and to decide definitely whether the electric light should be introduced into the city. The Mayor explained that the Corporation had obtained a Provisional Order at a cost of about £450, and had offered the same to the Brush Company on certain conditions. Mr. R. Percy Sellon said there had been considerable delay since the Corporation and the Brush Company first entered into negotiations, the Company from the first assuming that local support would be readily forthcoming if a local company were formed. He thought much apathy had been shown towards the undertaking by the citizens, and they had experienced difficulty in obtaining the services of local gentlemen to form a Board of Directors. This had caused some delay, but the Corporation met the Company generously, and gave them an extension of time, which had nearly expired, and the matter must at once be definitely settled. It had been clearly shown from the experience of the past ten years that electricity could not pay, when all the necessary expenses had been met, unless the demand reached between 3,000 and 5,000 8-c.p. lamps. If the Company had a demand for 4,000 lamps the undertaking would just pay. They (the Company) were prepared to come forward with two-thirds of the necessary capital, provided the other third was subscribed locally, the total required being between £15,000 and £20,000. It was necessary that the inhabitants should show goodwill towards the undertaking, and this could be done by subscribing the necessary £6,000 towards the capital expenditure. He calculated that the charge for current would be between 7d. and 8d. per unit, and electricity at that price would be equal, light for light, to gas at 3s. per thousand. He thought they need fear no diminution of the gas company's dividends, as it had been found that the introduction of the electric light had had an opposite effect. Alderman Mason said the scheme had met with a considerable amount of opposition from gas share-

Digitized by Google

holders, who were receiving 8 or 8½ per cent. dividends; but it must be remembered that these shares sold at twice their nominal amount, which would bring the dividends down to about 4 per cent., and this was what they might reasonably expect from the electric lighting undertaking. A resolution was ultimately adopted that "it was the opinion of the meeting that the electric light should be introduced forthwith into Canterbury," and a committee was appointed to carry this resolution into effect.

CAOUTCHOUC.—It is stated that new clusters of *ficus elastica* have been discovered on the Rivers Verde, Tarvo, Itenes, San Martin, Paragua, and their tributaries in the Bolivian Republic.

CENTRAL LONDON RAILWAY BILL.—The Royal assent was given on Tuesday last to the Central London Railway (Extension of Time) Bill.

CHATHAM.—The Highway and Works Committee of the Town Council have recommended that the Local Electric Light Company be called upon to at once remove their overhead wires, and, failing compliance, that the Board of Trade be consulted on the matter.

CHURCH AND CHAPEL LIGHTING.—At a meeting of the Electric Lighting Committee of the Hull Corporation last week, Dr. Holder, the Chairman, stated that the result of the negotiations with the representatives of Waltham Chapel was indicated by the following resolution. He moved: "That, inasmuch as the Sunday demand for electricity will, when winter approaches, require a Sunday shift of workers at the station, and as such a shift can work the whole number of machines as easily as it can one, it is desirable to foster the demand for light for illuminating churches and chapels. As an inducement this Committee recommends the Council to supply places of worship requiring it at a charge of 5½d. per unit for such electricity as they may use in such places, or in class-rooms attached thereto." The motion was carried, although Councillor Millington took exception to the resolution on the ground that it would necessitate Sunday labour on the part of Corporation officials.——The Church of St. Mary Redcliff, Bristol, which is considered the finest parish church in England, is about to be lighted by electricity. The Lady Chapel at Bristol Cathedral is now lighted electrically.——The Roman Catholic Church of St. Mary's, Barrow, to which extensive alterations are now being made, is to be lighted throughout by the electric light.——St. Peter's Church, Lancaster, is lighted by electricity.——The parish church at Eastbourne, which dates back to the twelfth century, is now being fitted for lighting by electricity.

EDINBURGH.—It has been decided by the Cleaning and Lighting Committee of the Town Council to recommend that George-street, St. Andrew-square, Charlotte-square, and the streets leading from these main thoroughfares into Princes-street be lighted by electricity.

ELECTRICAL ENGINEERING IN SOUTH AFRICA.—It is reported that Messrs. Siemens and Halske, of Berlin, intend to establish an electrical plant in the Witwatersrand mining district of South Africa, to supply electrical energy for pumping, boring, and other purposes.

ELECTRIC TRACTION IN GERMANY.—At the annual meeting of the Union Electrical Company of Berlin, held a few days ago, it was stated that the Company, which exploits the Thomson-Houston system in Germany, had, during 1893, completed electric tramways on that system at Bremen and Remsteid. During the same year work was also commenced of a similar character at Hamburg, Erfurt, and Gotha. The Company had recently received a further contract for converting an additional 70 kilometres of tramway at Hamburg for electric traction, the commission including the supply of 105 motor cars.

ELECTRIC TRACTION IN FRANCE.—The French Thomson-Houston Company has secured the contract for the construction of an electric tramway at Montpellier, and also the contract for converting several of the horse-car lines at Roubaix into electric tramways. The Lyons-Oullins electric tramway is to be extended to Saint-Genis, Laval.

ELECTRICITY IN MINES.—The Cowpen Coal Company are introducing at their Cambois Collieries a system of electric pumping, and electric pumps are to entirely supersede those at present driven by rope. About 20 miles of cable will be used.

FAREHAM.—A petition has been presented to the Board of Trade against the purchase of the Fareham Electric Light Company's undertaking by the Local Board.

FLEETWOOD.—The Improvement Commissioners have discussed the Electric Lighting Committee's report just presented. The report deals with the visit of the Fleetwood deputation to Coatbridge and other towns, and describes the nature of the works adopted. The system adopted for Fleetwood is on exactly the same lines as those at Coatbridge, with the exception of the gas tank, which at Fleetwood is to be increased, and made capable of holding a large supply of gas for engines during the hours of light and heavy loads. Tandem type engines, made by Messrs. Dick, Kerr and Co. are to be used, and rope-driving has been selected. The Brush Company have prepared the plans for the works. Mr. Kirkbride's tender for the buildings, &c., has been provisionally accepted; and Mr. C. Drummond has been appointed clerk to the works and engineer to superintend the building, &c. The total estimated cost is £11,819, which includes £500, which the Committee propose shall be expended for the purchase of electric fittings for sale to intending consumers. If this latter suggestion is approved it is proposed to fit up a show room in the central part of the town for displaying the fittings. The Committee anticipate no difficulty in obtaining approval from the Local Government Board for borrowing the necessary money. The report was unanimously approved.

GLASGOW.—At the last meeting of the Lighting Committee of the Town Council the report showed a steady increase in the demand for electric lighting for domestic purposes. All available plant is now fully employed, and considerable extensions are taking place with a view to meeting the coming winter's demands.

HAMPSTEAD.—The Electric Lighting Committee of the Vestry, having considered the applications sent in for the vacant post of Electrical Engineer, have selected six candidates who are to appear before the Vestry at its next meeting.

HOSPITAL LIGHTING.—The New Park Hospital at Hither Green, to be built for the Metropolitan Asylums Board from designs by Mr. E. T. Hall, F.R.I.B.A., is to be fitted throughout for the electric light, telephones, fire appliances, and with hydraulic lifts for the patients.

ILFRACOMBE.—The Local Board have received an intimation from the Great Western Electric Light Company of their intention to apply to Parliament for a Provisional Order for lighting the district by electricity.

ISLINGTON.—The Electric Lighting Committee of the Vestry have decided to recommend that the designs for the electric lighting central station sent in by Mr. A. Hessel Tiltman, F.R.I.B.A., be accepted. The cost of the works is estimated at £17,540.

LARNE.—The Town Commissioners have for the second time entered into a contract with the liquidators of Messrs. J. E. H. Gordon and Co. for the lighting of the town by electricity.

LONDON COUNTY COUNCIL.—The Works Committee decline to undertake the electric lighting installation works for Westminster and Waterloo Bridges and the Victoria Embankment on the ground that the Highways Committee's estimate for the work is much too low. The Highways Committee at the last meeting of the Council proposed that the work be offered to tender, and this proposal is to be considered at the next meeting.——The Highways Committee at the last meeting of the Council recommended that machinery and plant for the electric lighting station required for the installation for the Victoria-embankment and the Waterloo and Westminster Bridges should be immediately obtained, and that tenders asking for the supply of the machinery and plant be invited by public advertisement. It was suggested that as the designs for the lamp-posts proposed to be used had been generally condemned, premiums should be offered for good designs. After some further discussion the subject was adjourned until next meeting.

LYONS EXHIBITION.—During his visit to this Exhibition the late President Carnot was much interested in the exhibit of M. Croizier, the agent in France of Messrs. Willans and Robinson (Limited). There are on view a Willans-Siemens and a Willans-Crompton compound engine and dynamo, each producing 900 amperes at a potential of 120 volts, and generating three-fourths of the current used for lighting the cupola.

OLDHAM.—The Oldham Central Electric Supply Station has just been completed by Messrs. J. P. Hall and Co. The same firm have also lately completed contracts for electric light installations for the Manchester Ship Canal Company for the locks at Barton, Irlam, and Latchford, the plants for which comprise arc lamps, dynamos, steam engines, boilers, &c.

PADDINGTON.—The Vestry have received a request from a prominent ratepayer asking them to ascertain from the Metropolitan Electric Supply Company and other companies if they are prepared to enter into arrangements for lighting the streets of Paddington, either partially or otherwise, by electricity, and at what cost.

PROVISIONAL ORDERS.—The Royal assent has been given to the Provisional Order for the electric lighting of St. Austell.

SHOP AND WAREHOUSE LIGHTING.—The extensive new premises recently opened by Mr. Clark at Bayswater, W., are to be lighted electrically throughout by Messrs. John Bowling and Sons (Limited).

SHOREDITCH.—The Electric Lighting Committee have applied to the London County Council for a loan of £12,300 for sixty years.

SOUTHAMPTON.—Notice has been received by the Town Council from the Southampton Electric Lighting Company of their intention to apply for a Provisional Order in the ensuing session.

SOUTH SHIELDS.—A visit has been paid by the Mayor of South Shields, accompanied by two Aldermen, the Town Clerk (Mr. Moore Hayton), and Mr. Joseph Jeckell, the electrical engineer, to

Digitized by Google

Bristol, for the purpose of inspecting the electric light works in that city.

THEATRE LIGHTING.—The electric lighting at the Theatre Royal, Bradford, is used for the auditorium, entrance corridors, bars, and footlights. There is sufficient plant and power to supply in addition the stage, dressing-rooms, scene-dock, and workroom in the rear. 454 16-c.p. incandescents have been provided for the auditorium. In the covered space in front of the theatre 56 incandescents and three arcs are used, while a 3,000 c.p. arc is placed on the top of the building. The central electrolier in the auditorium is provided with incandescents equal to 1,000 c.p.

TORQUAY.—The Holloway Electricity Supply Company have notified the Torquay Corporation of their intention to apply for a Provisional Order for lighting the district by electricity. The matter has been referred to the Electric Lighting Committee. The Corporation themselves possess Parliamentary powers.

WALTHAMSTOW.—At the last meeting of the Local Board a letter was read from Mr. Jerram, notifying the Board that a syndicate had been formed for supplying electric current in the district, and asking the Board's permission for opening the roads and laying down the necessary mains. The writer also inquired if the Board were willing to take electric current for street lighting at the same cost, or less, than they now paid for gas lighting. The letter was referred to the Lighting Committee.

WREXHAM.—The Town Council has affixed the Corporate Seal to a joint memorial from the Wrexham and District Electric Supply Company (Limited) and the Corporation to the Board of Trade, in reference to the proposed acquisition by the Corporation of powers, under Provisional Order, licence, or otherwise, for supplying electric current within the borough, and asking that the Corporation may become the undertakers for such supply in place of the Company. The memorial states that the price to be paid by the Corporation to the Company is £350.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

June 11, 1894.

11,276. R. LANGHANS. London. Improvements in and relating to electric incandescent lamps.

11,280. W. GEIPEL. London. Improvements in jointing electric conductors.

11,286. H. C. L. HOLDEN. Woolwich. Improvements in electric arc lamps.

11,312. H. H. LAKE. London. Improvements in electric accumulators or secondary batteries. (La Société Electrogénique, France.)

11,320. H. H. LAKE. London. Improvements relating to telegraphic and telephonic transmission. (M. J. Pupin, United States.)*

11,323. A. MUIRHEAD and A. FRASER. London. Improvements in apparatus for the automatic transmission of signals through telegraph lines and cables.

11,338. C. M. HOUGHTON. Cheltenham. System of electric signalling. (L. F. C. Rich, United States.)

June 12, 1894.

11,339. L. HOFFER. London. Improvements in cigarette paper and in holders therefor.

11,364. W. LOWRIE. London. Improvements in dynamo electric machines.

11,418. J. E. KINGSBURY. London. Improvements in telephone transmitters. (The Western Electric Company, United States.)

June 13, 1894.

11,439. H. J. WAGG. London. Improved electric indicator.

11,452. R. E. B. CROMPTON and H. J. DOWSING. London. Improvements in connectors for conductors used with electrical apparatus.

11,483. J. E. LIARDET. London. Improvements relating to the generation of electricity.

June 14, 1894.

11,559. H. LÜDEKE, E. L. A. LÜDEKE, A. J. THORMAN, E. DE BUNSEN, and E. M. HORE. London. Improvements in magneto-electric motors.

11,587. L. P. HULIN. London. Improvements in the process of and apparatus for the electrolytic decomposition of solutions, and for the immediate separation therefrom of the liquid or dissolved electrolytic products. [Date applied for under Patents, &c., Act, 1883, Sec. 103, November 25, 1893, being date of application in France].

COMPANIES' MEETINGS AND REPORTS.

Oriental Telephone and Electric Company (Limited).

The first ordinary general meeting of this Company was held on Wednesday at Winchester House, Old Broad-street, under the presidency of Mr. W. Addison.

The SECRETARY (Mr. Alex. B. Chalmers) having read the notice convening the meeting,

The CHAIRMAN said : Gentlemen, the Directors of the newly-constructed Company have the pleasure of meeting you to-day at what is termed the "statutory general meeting," which by Act of Parliment is required to be held within four months from the formation of the Company. The meeting has not been held earlier because we were desirous of being able, when it was held, to inform you that the reconstruction arrangements had proceeded satisfactorily. This, we are glad to inform you, has, in all respects, been the case. The new Company was registered on the afternoon of the same day on which the resolutions were passed by the shareholders of the old company, and the business has been continued by the new Company without drawback of any kind, nor is any anticipated. In order to obviate, as far as possible, inconvenience to shareholders, the application for a quotation on the Stock Exchange of the shares in the new Company was pressed forward as much as possible, and, with the assistance of the representatives of the Stock Exchange, the necessary arrangements were concluded promptly and satisfactorily. Few transfers of shares have taken place, from which it may be inferred that the shares are well and firmly held. I am also pleased to inform you that the Company's business is showing fair progress. The reports from its various agencies and from the affiliated Companies are satisfactory. As regards India, the volume of business transacted shows a satisfactory increase ; but it is only right that I should remind you that the depreciation of silver may affect the net revenue. We can only hope that silver has already reached its lowest price, and that any movement in the future may show an upward tendency. The new Company having only been formed on March 12th, we cannot at this meeting bring before you the usual annual report and balance-sheet, but will do so at the earliest opportunity next year, which will probably be, as usual, in April, when the results of the Company's operations to the end of the present year will be laid before you. As there is no special resolution to put before the meeting I shall be happy to answer any questions that may be asked.

No questions being asked,

The CHAIRMAN (after a pause): Well, gentlemen, this is only a formal meeting, as you are aware, and that concludes the business.

The meeting then separated.

The India-Rubber, Gutta-Percha, and Telegraph Works Company (Limited).

A half-yearly general meeting of the Company was held at the Cannon-street Hotel yesterday for the purpose of obtaining the sanction of the shareholders to the payment of an interim dividend of 5 per cent., or 10s. per share, free of income-tax. Mr. S. William Silver presided.

The SECRETARY (Mr. W. J. Tyler) having read the notice calling the meeting,

The CHAIRMAN said : Gentlemen, the books are made up, as I think you are aware, only once a year. I have no hesitation in recommending for your adoption

"*That an interim dividend of 5 per cent., or 10s. per share, free of income-tax, be payable on the 6th inst.*"

When we last met I referred to the considerable difficulty we experienced in securing contracts and works generally owing to the depression in trade that exists. This state of things has increased. Notwithstanding, I think that we get our share. This is to be accounted for by the efforts used to make known, both at home and abroad, the excellency of the work turned out at Silvertown, and the efficiency of the machinery, which is quite up to the requirements of the hour—so much so that I may say that we have the first offer of most improvements introduced into this country. Now, here let me say that I would ask you all who are interested in this concern to use any and every opportunity of bringing business that may present itself to you. As regards submarine cable work we have done very little besides laying a short length for the Spanish Government ; but we have had a fair share of land work, including orders from our own and foreign Governments. The works at Silvertown are in a very efficient state, and I think I may say that the same remark applies to those at Persan.

Mr. SCOTT seconded the motion.

Mr. M. GRAY said that he had recently visited the works at Persan, and found them in very good order ; and he was in every way satisfied with the manner in which the business was being conducted, not only there, but at Silvertown.

The motion was carried unanimously.

Dr. SMALL proposed, and a SHAREHOLDER seconded, a vote of thanks to the Chairman and Directors ; and,

The CHAIRMAN having expressed his acknowledgment, the proceedings ended.

Eastern Telegraph Company (Limited).

The following is the report for the half-year ended March 31, 1894, to be presented to the forty-fourth half-yearly ordinary general meeting, to be held at Winchester House, London, E.C., on Thursday next, the 12th inst., at one o'clock :—

The revenue for the six months ended March 31, 1894, amounted to £389,314. 2s. 3d., from which are deducted £102,218. 18s. 6d. for the ordinary expenses, and £49,660. 6s. 5d. for expenditure relating to repairs and renewals of cables, &c., during the half-year. After providing £3,219. 14s. 8d. for income tax, and £401. 12s. 6d. due to re-valuation of currency, balances at stations, &c., there remains a balance of £233,813. 10s. 2d., to which is added £86,252. 13s. 11d. brought from the preceding half-year, making a total available balance of £320,066. 4s. 1d. From this balance there have been paid—

Interest on Debentures and Debenture Stock.....	£27,680	4	0
Dividend on Preference shares	20,384	11	11
An interim dividend of 2s. 6d. per share on the Ordinary shares	50,000	0	0
	£98,064	15	11

Leaving a balance of £222,001. 8s. 2d., from which £110,000 has been carried to General Reserve Fund.

The Directors now recommend the declaration of a final dividend for the year ended March 31, 1894, of 2s. 6d. per share and a bonus of 3s. per share, amounting together to £110,000, both payable on the 12th instant, free of income-tax, and making, with the three previous payments on account, a total distribution of 13s. per share or 6½ per cent. for the year on the Ordinary shares. The balance of £2,001. 8s. 2d. shown at the foot of the revenue account is proposed to be carried forward to the next half-year.

The revenue includes £32,791. 12s. dividends and bonus for the half-year upon the Company's investments in the Eastern and South African, the Black Sea, the Direct Spanish, and the African Direct Telegraph Companies.

West African Telegraph Company (Limited).

Report of the Directors for the year ended December last, to be presented to the ninth ordinary general meeting to be held at Winchester House, E.C., on Thursday, the 12th inst., at 2:30 :—

The Company's revenue for the period amounted to £61,847. 1s. 5d., against which £18,828. 19s. 1d. is charged for ordinary expenses, and £20,492. 5s. 11d. for expenditure relating to repairs to cables, &c. After

Digitized by Google

providing £1,020. 6s. 1d. for Income-tax, and £214. 8s. 3d. due to revaluation of currency balances at stations, there remains a balance of £21,285. 2s. 1d., to which is added £2,410. 9s. 10d. brought forward from the preceding year, making a total balance of £23,695. 11s 11d. From this balance there is deducted £12,495. 11s. 11d. for interest on debentures, and £11,200 for sinking fund.

The total expenses attending repairs and renewals of cables, &c., amounted to £31,233. 17s. 6d.; but the Directors, after careful consideration, have decided to apply from the general reserve fund the sum of £10,741. 11s. 7d. to meet the deficiencies which would otherwise have appeared after providing for the ordinary expenses, interest and sinking fund for debentures, as well as for the expenses incurred in repairing the cables.

A loss has been made on exchange of £7,751. 2s. 10d., against £8,044. 10s. 1d. last year. The depreciation of Portuguese currency continues to seriously affect our remittances from abroad.

The Directors who retire by rotation are Sir John Pender, G.C.M.G., M.P., and Mr. Thomas Fuller, who, being eligible, offer themselves for re-election, as do the auditors, Messrs. Deloitte, Dever, Griffiths and Co.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1894, pages 274-300, *&c., &c.*]

BELCHER'S PATENT SMOKE PREVENTER COMPANY (LIMITED).—This Company was registered on July 2nd with a capital of £1,000 in £1 shares, to acquire letters patent, No. 9,340, of May 17, 1892, for improvements in or connected with the furnaces of steam boilers, and to carry on the business of manufacturers of boilers, furnaces, and engines of any description, and general engineers.

COMMERCIAL ELECTRICITY SUPPLY COMPANY (LIMITED). — This Company was registered on June 30th, with a capital of £2,000, in £1 shares, to carry on the business of an electrical company in all or any of its branches, in particular to supply electricity for use in the production of light and power, and to carry on the business of electrical and mechanical engineers and manufacturers of and dealers in electric, magnetic, telegraphic, telephonic and other appliances, and steam, hydraulic, pneumatic or other engines. The subscribers (with one share each) are: Arthur E. Cosson, 96, Hillfield-road, West Hampstead, N.W.; Arthur J. McGrath, 70, Victoria-road, Kentish Town, N.W.; George W. Whitton, 60, Queen Victoria-street, E.C.; Robert A. Daniell, 20, Bucklersbury, E.C.; Frederick G. Nash, 73, Salcott-road, Wandsworth Common, S.W.; Edward L. C. Bauman, 67, White Horse-lane, Mile End, E.; Samuel G. Tripp, 28, Wilberforce-road, Finsbury Park, N.

CROPPER-MINERVA MACHINES COMPANY (LIMITED).—This Company was registered on June 28th with a capital of £10.000 in £1 shares, to acquire by purchase or otherwise, and carry on the business of machine builders, engineers, and to carry on the business of an electric light company in all or any of its branches, to construct, lay down, establish, fix, and carry out all necessary cables, wires, lines, accumulators, lamps and works; to generate, accumulate, distribute, and supply electricity, and to carry on the business of electricians, suppliers of electricity, manufacturers of electrical apparatus, &c.

DALZIEL'S NEWS (LIMITED).—This Company was registered on June 30th, with a capital of £150,000, divided into 60,000 £6 per cent. cumulative Preference and 90,000 Ordinary shares of £1 each, to acquire as a going concern the business of a news agency carried on by Dalziel's Cable News Agency (Limited).

GREAT WESTERN ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—This Company was registered on June 29th with a capital of £1,000 in £10 shares, to produce and supply electricity or electrical currents and force, to undertake public or private lighting, to supply light, heat, motive power, or telegraphic, telephonic, or other means of communication, to make applications to Parliament, the Board of Trade, or any Municipal, or other authorities or persons for powers, grants, or concessions for public or private lighting, and to manufacture, provide, sell, deal in or let for hire any engines, machinery, wires, plant, instruments, fittings or apparatus for producing, storing, supplying, transmitting or using, or for regulating and measuring the supply or consumption of, or for facilitating the use of, electricity. The subscribers (with one share each) are:—H. G. Simmonds, 73, St. George's-avenue, N.; William Farrant, 7, Vincent-square, S.W.; R. Bridges-Molesworth, 34, Victoria-street, S.W.; Arthur H. Witham, 49, Crewdson-road, Brixton-road, S.W.; Erasmus A. Watts, 74, Offord-road, Barnsbury, N.; Edward L. Russell, 2, Thornford-road, Lewisham, S.E.; Arthur G. Defries, Rose Bank, Bulwer-road, Leystonstone, E.

ALFRED HERBERT (LIMITED).—This Company was registered on July 2nd, with a capital of £25,000 in £5 shares, to acquire the business of a mechanical engineer and manufacturer of boilers, engines, tools, and implements carried on by Alfred E. Herbert, at the Butts, Warwick, and to carry on the business of mechanical engineers, machine and engineering tool makers, fitters, boiler makers, iron and brass founders, millwrights, steel converters, plate makers, electrical engineers, suppliers of electricity for all purposes, wire drawers, tube makers, &c.

NON-CORRODING SILVER METAL SYNDICATE (LIMITED).—This Company was registered on June 20th, with a capital of £20,000, in £1 shares, to acquire, use and operate an invention or process for a silver metal having a greater tensile strength than that of steel, capable of taking and maintaining a high polish, and not susceptible to corrosion or tarnish; and to carry on the business of manufacturers of machinery, engineers, mechanics, machinists, iron founders, &c.

ABRAM PULMAN AND SONS (LIMITED).—This Company was registered on June 28th, with a capital of £12,000 in £5 shares, to acquire and take over as a going concern the business carried on by Abram Pulman and Sons, at Halifax, to carry on the business of iron and steel merchants, bolt and screw manufacturers, metal workers, iron and brass founders, coppersmiths, machinists, metallurgists, &c., and to construct, equip, and supply electric motive power, and all kinds of machinery, appliances, apparatus, and things of every description in connection therewith.

PUTNEY ELECTRIC SUPPLY COMPANY (LIMITED).—This Company was registered on June 27th, with a capital of £1,000 in £2 shares, to enter into contracts for electric lighting, and for the supply of electric energy for power and transmission, and for fixing, maintaining, selling, hiring, or otherwise dealing with wires, lamps, secondary batteries, and all other electrical appliances and equipments, and to supply, or manufacture, purchase, hire, take in exchange, or otherwise acquire, sell, and supply all machinery, motors, generators, lamps, and materials connected with, or necessary to, the business of the Company. The subscribers are:—John S. Sayer (50 shares), Samuel Legg (1), William Goodridge (1), Ernest R. Smith (1), Herbert A. Hughes (1), Thomas C. Cleary (1), and William B. Ducket (1).

THOMAS RICHARDSON AND SONS (LIMITED).—This Company was registered on June 21st, with a capital of £250,000 divided into 20,000 Ordinary, and 5,000 £5 per Cent. Cumulative Preference shares of £10 each, to acquire and carry on the business of marine engine builders, mechanical engineers, founders, smiths, machinists, manufacturers, and patentees, carried on at the Hartlepool Engine Works, Hartlepool, in the County of Durham, by the firm of Thomas Richardson and Sons. The first Directors are Thomas Richardson (Managing Director), and William J. Richardson (Chairman).

TANDEM SMELTING SYNDICATE (LIMITED).—This Company was registered on June 28th with a capital of £5,000 in £1 shares, to acquire the business of dealing in Tandem-bearing and other anti-friction metals and alloys carried on under the style of "Hoveler and Dieckhaus," at 3, Stockwell-avenue, London, S.W., including the right of manufacturing such metals and alloys within the United Kingdom, and to carry on the business of analytical chemists, metal workers, smelters and manufacturers, brass founders, engineers, &c.

WINDERMERE AND DISTRICT ELECTRICITY SUPPLY COMPANY (LIMITED).—This Company was registered on June 27th, with a capital of £50,000, in £5 shares, to carry on the business of electrical engineers, electricians, engineers, and contractors, suppliers of electricity, manufacturers of and dealers in electrical apparatus, mechanical and chemical engineers, water power engineers, tramway proprietors, &c., and the business of producing, storing, distributing and supplying light, heat, sound and power by electricity, galvanism, magnetism or otherwise. The subscribers (with one share each) are: Martin E. Sheerboom, Arthur Barrenger, Thomas T. Bickford, James Renwick, Archibald Hair, H. E. Shaughnessy, and Frederick Hodson, all of London.

WIMSHURST, HOLLICK AND CO. (LIMITED).—This Company was registered on June 27th, with a capital of £40,000, divided into 4,000 £5 per Cent. Cumulative Preference and 4,000 Ordinary shares of £5 each, to acquire as a going concern a business of electrical and general engineers and boilermakers now carried on in Commercial-road, London, E., to manufacture and deal in all apparatus used in connection with the generation, distribution, supply, accumulation, and employment of electricity, and to carry on the business of electrical and general engineers, boilermakers, manufacturers, and electricians. The first Directors are: Thomas D. Hollick, Thomas P. Hollick, and Frederick W. Drake, the first mentioned being Managing Director.

CITY NOTES.

AFRICAN GOLD RECOVERY COMPANY (LIMITED).—Lord Kelvin, Sir Henry E. Roscoe, Prof. W. Crookes, F.R.S., and Mr. Le Neve Foster are, it is stated, to be witnesses in the action brought by the above Company against Messrs. Lake and Thompson in regard to the Company's gold recovery patents. The action is to be tried at Pretoria, but the evidence of the above gentlemen will be taken on commission.

CENTRAL CHILI COPPER COMPANY (LIMITED).—This is the title of the reconstructed Panulcillo Copper Company, with a capital of £255,000 in 30,000 Six per Cent. Cumulative Priority Shares of £1 each, and 225,000 Ordinary shares of £1 each. The Priority Shares are now offered for subscription to the shareholders of the old Company in the proportion of one Priority for every eight shares held in the old Company. Shareholders of the old Company subscribing for shares in the new are also entitled to receive two Ordinary shares of the new Company of £1 each fully paid in exchange for each share they hold in the Panulcillo Company. The Directors consist of Sir John Pender, G.C.M.G., M.P., and Messrs. Goldschmid, of Paris, and J. H. Collins, F.G.S., formerly of the Rio Tinto Company. Subject to conditions explained in the prospectus the Priority Shares will have preference both as to capital and interest. Copies of the prospectus can be obtained at the offices, St. George's House, Eastcheap, E.C.

CHILIAN MANGANESE MINES (LIMITED).—This Company, which has an authorised capital of £125,000, invites applications for £50,000 Seven per Cent. First Debentures, of which £17,200 has already been subscribed for. The debentures are in £100. The property of the Company consists

Digitized by Google

of valuable manganese mines in Chili. Mr. Joseph Wilson Swan is Chairman of the Company.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended July 1st were £1,020, as against £811 in the corresponding period of 1893, being an increase of £209. The total receipts for the half-year amount to £23,636, as against £22,610 for the corresponding period of 1893, an increase of £1,026.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The warrants for the interest due on this Company's debenture stock to June 30th have been posted. The transfer books and register of members of the Six per Cent. Cumulative Preference Shares of this Company are announced to be closed from July 9th to 19th inclusive, to enable the preparation of the interim dividend warrants.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of June are £3,350, as compared with £3,233 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—This Company's estimated traffic receipts for the month of June amounted to £1,617, as against £1,730 in the corresponding period of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of June amounted to £53,752, against £62,564 in the corresponding period of last year, being a decrease of £8,812.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of June, 1894, amounted to £44,244, and to £45,443 in the corresponding period of 1893.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED). An extraordinary general meeting of this Company was held on Tuesday, at the Cannon-street Hotel, Mr. J. S. Forbes in the chair. On the motion of the Chairman, seconded by Major Flood Page, a resolution approving of the provisional agreement of June 5th last between the Swan United Electric Light Company (Limited) and this Company for the sale of the Swan Company's undertaking to this Company for debenture stock, was passed. The Chairman said that when the two companies originally came to terms there were "two Richmonds in the field," the Edison and the Swan, both with patents of a useful character, that might have led to litigation; but instead of fighting they amalgamated, and did pretty well under that amalgamation. But, whereas the Swan had patents in Great Britain, all Europe, and some other places, the Edison Company had only the British patents; therefore, all the Edison Company put into the pot as the Swan Company was the British patents, and kept the outlying business as a separate matter, and that was now represented by a business in Germany, certain advantages there, by an investment in the French Edison Company, and so forth. Now they proposed to bring it in. The patent period was now over. They were the subjects of active competition, and, this being so, came to the conclusion that it was very desirable to join forces, so as to present a united front to the enemy, not only in Great Britain, but also on the Continent, and for that residuum the Swan Company had agreed to accept £100,000 of debentures. The question to determine that day was whether the Edison and Swan Company was willing to give that for it. The Boards of both companies had agreed to the scheme, but preferred to have the approval of the Edison and Swan proprietors. Major Flood Page said that every single Director and every official connected with the management of the organisation was in accord in thinking that if they were to make a success of that undertaking they must have this fusion, in order to show a united front against all the rivals they now had in this business. Col. Stroud asked when the meeting for the presentation of the accounts would take place. And the Chairman (Mr. J. S. Forbes) replied that it would be held on July 26th.

SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—An extraordinary general meeting of this Company was held at the Cannon-street Hotel, on Tuesday, Mr. J. S. Forbes presiding, when the special resolution passed at the extraordinary general meeting held on the 14th, and published in *The Electrician* on June 8th (page 169), was, on the motion of the Chairman, seconded by Major Flood-Page, confirmed. Colonel Wallace Stroud inquired in what way the £100,000 of Debentures to be given to the Swan Company were to be secured, and what would be their value, and in reply the Chairman stated that the £100,000 of Four and a-Half per Cent. Debentures would be secured on the property of the Edison and Swan United Electric Light Company, and, of course, would be a preference charge on the profits of that undertaking. What would be the worth of such debentures he could not say but he believed they would be a gilt-edged security. No doubt the patents were gone—and they cost a considerable portion of the capital—but the business remained, which, if properly administered, would return good profits from year to year.

ELMORE'S PATENT COPPER DEPOSITING COMPANY (LIMITED).—The Directors of this Company summoned a meeting of the shareholders at the Cannon-street Hotel, yesterday (Thursday), for the purpose of receiving their resignation, and appointing new Directors. The Directors in their circular say:—"It will be in your recollection that the investigation committee recommended, in the first instance, that local Directors should be selected; but, that being impossible at the time, the present Directors were appointed. Their work has been done at much inconvenience to themselves, to the best of their ability in the interests of the shareholders; but they feel it most difficult to exercise a proper control over the business without a sacrifice of time which their other occupations render most inconvenient. They are desirous, therefore, of placing their resignation in the hands of the shareholders, and are, they believe, fully justified in so doing under the conditions which are such as will enable them to present to the meeting the names of local gentlemen of position and ability who are now willing to take over the direction of the Company's affairs. It will be evident that the position of the business and condition of the works must be greatly improved, or the proposed new Directors would not have been induced to come forward and take a large pecuniary interest in the business, and place themselves in the responsible position of controlling the affairs of the Company. After the last meeting £10,000 of Six per Cent. Debentures were offered to the shareholders, but, as the issue met with little response, the deposits were returned. The want of capital caused again delay in developing the business, and it was only after some time that an arrangement was come to with our bankers (through the agency of Mr. William Elmore and the guarantee of Mr. A. S. Elmore) to the extent of £15,000. This provides for the purchase of ample supplies of copper and the completion of the needful plant; so that nothing should now be wanting for the accomplishment of profitable results. The Wire Company having obtained capital, an arrangement must now be made with them for the joint use of the furnaces, and, as other important agreements are waiting completion, the present Directors are desirous that they should be entered into by the new Directors, who would then commence their duties with a fuller control of the interests of the business."

At the meeting yesterday, the Chairman explained that the reason why the Directors wished to retire from the Board was that they were not sufficiently in touch with the business of the Company to effectively control it. Mr. Elmore had secured the services of three gentlemen who were willing to take over the direction of their affairs, and he was quite sure that the interests of the shareholders would be very much better looked after by them than could possibly be done by the existing Board, for the reason that they were more acquainted with the details of the trade. The new Directors lived near the works, and could, therefore, exercise the necessary control over the affairs of the Company which was absolutely required before economical and profitable results could be obtained from its business. Messrs. John Marshall (Sunderland), John North (Leeds), and Edward Reynolds (Sheffield) were then appointed Directors.

ELMORE'S GERMAN AND AUSTRO-HUNGARIAN METAL COMPANY (LIMITED).—It is stated that Mr. Rock, owing to continued ill-health, has resigned his seat on the Board of this Company, his place being taken by Mr. John Heel, of the firm of Bloor and Heel, of Snow-hill, E.C.

KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING COMPANY (LIMITED).—A dividend for the half-year ending June 30th on the Six Per Cent. First Preference Shares of this Company will be paid on and after the 13th inst.

LIVERPOOL ELECTRIC SUPPLY COMPANY (LIMITED).—It will be noticed from our share list that the stock of this Company is now all fully paid.

NATIONAL TELEPHONE COMPANY (LIMITED).—This Company announce a scheme of conversion and redemption of £1,000,000 Four and a-Half per Cent. Debenture Stock by the issue of £1,100,000 Three and a-Half per Cent. Debenture Stock, forming part of a total amount of such stock limited to £2,000,000. Holders of the Four and a-Half per Cent. Debenture stock are notified that unless presented for conversion under the present scheme, their stock will cease to bear interest and will be redeemed on December 31st next. Existing Four and a-Half per Cent. Debenture-holders will receive allotment in full at the rate of £110 of the new stock for every £100 of the old stock, and 6s. 6d. in cash (less tax) upon allotment, being the difference between the £110 stock of 3½ per cent. and the £100 Four and a-Half per Cent. Cash subscriptions for the remaining Three and a-Half per Cent. Stock will be received at par. The new Three and a-Half per Cent. Stock will constitute a first charge on the entire undertaking and property of the Company. The list for subscriptions will be closed at 4 p.m. on Wednesday, the 11th inst. The list for cash subscriptions opened on Saturday last and closed on Tuesday.

ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED).—The Directors announce an interim dividend for the half-year ended June 30th at the rate of 7 per cent. per annum on the Preference shares, and at the rate of 4 per cent. per annum on the Ordinary shares.

WEST AFRICAN TELEGRAPH COMPANY (LIMITED).—Notice is given of the drawing of 116 Five per Cent. Mortgage Debentures of £100 each in this Company. The debentures will be paid off at par on September 1st next at the National Bank of Scotland, Nicholas-lane, Lombard-street, E.C.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended June 29th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £2,370.

CRICKET.—EASTERN TELEGRAPH COMPANY—HEAD OFFICE *v.* COMPANY'S SHIPS.—A match was played on Saturday last on the West London Cricket Ground between teams representing the head office staff and the officers of the Company's ships now in London, resulting in a victory for head office by 43 runs.

Scores:—Head Office: H. J. Burke, b Bonitto, 38; W. M'Intosh, b Bonitto, 1; T. J. Palmer, b Drake, 13; G. C. Jack, c Denton, b Bonitto, 19; J. G. Macmillan, b Bonitto, 46; A. G. THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 843.—Vol. XXXIII. FRIDAY, JULY 13, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

On Monday *The Times* gave publicity to some rather unnecessary queries addressed to the Postmaster-General by Mr. Henniker Heaton, M.P. If the member for Canterbury had taken the trouble to obtain the copy of the National Telephone Company's licence he would have been able to secure all the information he wanted without wasting the time of the Postmaster-General and looming large in the public eye in the columns of the newspapers. However, it is some satisfaction to know that the Post Office has an opinion in matters telephonic, and that opinion a decidedly definite one. According to the Post Office reading of the National Telephone Company's licence the right of the National Telephone Company to carry on telephone exchange business will absolutely cease and determine on the termination of the licence in December, 1911; and all they will have to sell will be their plant, and even this the Government will be under no obligation to buy. With this view, any other than which is inconceivable, so clearly stated in 1894, the shareholders of the Company cannot in 1911 raise the cry of confiscation, when their property is bought up at a knock-down price by the State. The general policy of allowing private capitalists to flourish exceeding well for a short time, on the condition that they consent to be swallowed up afterwards with or without a murmur, is not indeed one which is calculated to encourage thrift, genuine private enterprise or good service; but if the terms of such contracts are explicitly stated and kept well before the public, there really can be no ground for accusations of unfair treatment.

The London County Council and the promoters of the proposed electric railway to Epping Forest are to be congratulated upon having hit on a timely compromise, the full terms of which will be found in another column, as regards what appeared to be an irreconcilable difference of opinion as to the running of workmen's trains. Ample, cheap, and rapid communication between the business centres of this great city and its suburbs is, it is generally agreed, the most certain way of preventing that overcrowding which all deplore; and the Greathead tube combined with the electric train would appear to be the combination above all others that is likely to secure these *desiderata*. But unless our municipality undertakes to build and run these lines at the expense of the ratepayer, which the gods forbid, it is mere midsummer-madness to impose such onerous conditions upon capital that even company-mongers, who are notoriously over-sanguine, refuse to accept them. Half a loaf is better than none, and workmen, if they are constituted like other men, which we are given to understand is still the case, will probably prefer to be temporarily charged the not extravagant sum of 4d. for an eighteen-mile ride rather than go without a ride at all until the capitalist has been disciplined into taking them nine miles for one penny. Of course it is quite right and proper that someone should look after the public interest and see to it that excessive profit is not made out of the transit necessities of the workers of the metropolis; between the extremes of *laissez-faire*, however, and pedantic obstinacy, there is a mean which is in all senses of the word golden.

Anyone who knows murky Manchester will be a little astonished to find that the reason assigned by the Gas Committee of that city for the serious reduction in the consumption of gas during the past year is the "unusually bright weather during the greater part of the year, and the almost entire absence of fogs during the winter months." We fancy we have heard this several times before. It is, however, comforting to find the confession that "the extended use of the electric light" has contributed something towards this result. In Manchester the gas and electric light interests are hand-in-glove, being controlled by the Corporation; but, in some other places, their rivalry has led gas companies to accept any sort of explanation of the falling-off in gas consumption rather than admit that the rival luminant could have produced one iota of effect.

The Directors of the Morecambe Electric Light and Power Company have, it is stated, announced an advance in their charges for energy as follows:—For 8-candle lamps, from 10s. to 12s. per annum; for 16-candle lamps, from £1 to £1. 0s. 4d.; and for 32-candle lamps, from £2 to £2. 8s. per annum. The reason officially given for this advance is said to be that "the excessive and unjustified use of the light by many consumers, combined with the cost of production, has compelled the Directors to adopt this course to insure an adequate return on the shareholders' capital." Is it possible that the Directors expect, by such a course as this, to reduce the "excessive and unjustified use of the light"? If so, we fear they will be disappointed. They are but experiencing one of the inevitable results of a combination of the "fixed rental" system with human nature as it exists in the present year of grace. Economy at the lamps will only occur when the consumer, unregenerate man that he is, sees it to be to his

Digitized by Google

advantage. An increase in the fixed rental will only lead him, prompted by his old Adam, to leave the current on longer than before. Salvation to the supply company lies only in the adoption of a meter tariff.

THE large-scale example of Dr. LODGE's "coherer" experiment, described by Prof. ELIHU THOMSON in our correspondence columns this week, is very interesting. To perform this experiment you take a thunderstorm, some Smee cells, bad contacts, and a plating bath. The bad contacts offer a considerable resistance, necessitating an excess of battery power; all goes well until you turn on the thunderstorm, when the bad contacts break down, the cells boil, and the work in the bath is ruined. Prof. THOMSON says that "the secret came out" on an inspection of the connections; but it is not every one who could recognise that under these circumstances a flash of lightning would cause coherence of badly-conducting surfaces. Prof. THOMSON remarks that we have practically little or no information about the waves which are propagated during thunderstorms. It seems probable, from the great variety of flashes which were visible during the storm on Friday last, that the complete study of such waves would be very difficult.

THE cathode rays about whose interesting peculiarities Dr. P. LENARD has recently told us so much, have not had to wait long before a more or less practical application has been made of their properties. In a communication to the Académie des Sciences last week M. ALBERT HESS proposes to make use of these rays for the purpose of obtaining a sort of inertia-less Ewing curve-tracer. M. HESS's idea is to allow cathode rays to fall upon a rapidly-moving photographic film, and to place the whole "observing space," as Dr. LENARD calls it, within the variable magnetic field to be investigated. The curve obtained would not thus be in any way distorted by the inertia of moving parts, and there need not, therefore, it would seem, be any limit to the frequency of the magnetic field. An absolutely inertia-less index pointer is a desideratum in many other instruments than the one proposed; and it is possible that if a cathode beam turns out to be a successful pointer in this latter instrument, we may soon see a large quantity of other refined research apparatus similarly modified.

EXACTLY what the legal liability of a newspaper may be when it hazards a comment on a lawsuit in the state of suspended animation in which the action Brasyer *v.* Harness and Another now finds itself, we neither know nor propose to put to the test. It is permissible, however, to call attention to Mr. Justice CHARLES's definition of the "note of quackery." According to the learned Judge, a medical quack is one who professes that a single remedy will cure everything. The dictionary definition is a comparatively simple affair, and does not, it would seem, contain such serious implications as the judicial dictum. WEBSTER boldly labels a quack as one who "boastfully pretends to skill or knowledge of any kind not possessed." Should Mr. Justice CHARLES's phrase prevail over this very unmistakable indication, we are afraid the "note of quackery" will be struck by those innocent individuals who so persistently in season and out of season advocate "*tout par l'électricité*," and who will never be satisfied until everything, from express engines to curling tongs, is electrical.

Congress of Learned Societies.—The thirty-third Congrès des Sociétés Savantes is fixed for Tuesday, April 16, 1895.

French Association for the Advancement of Science.—This Association will hold its meeting at Caen from August 9th to 15th.

The Latest Transatlantic Cable.—The "Britannia" has arrived at Hearts Content, Newfoundland, with 190 miles of cable for the new Anglo-American cable.

Cable Interruptions:

	Date of Interruption.
Bissao-Bolama	Nov. 24th, 1893.
Sierra Leone-Accra	July 2nd, 1894.

Relative Resistances.—Prof. Kohlrausch, it seems, has made experiments with the purest water which he could obtain, and finds that a column of one inch has a resistance equal to a copper wire of the same cross-section passing twenty-five thousand times around the earth.

Electric Traction in Algeria.—The question of electric traction is now being considered at Algiers. It is proposed, in the first instance, to convert the horse-tramway between the Plateau Saulieu and the Hôpital du Dey, a distance of about 4½ kilometres, into an electric line on the overhead conductor system.

Magnetic Disturbances.—The report of the Kew Committee for the year 1893 states that as regards magnetic disturbances no very large movements were registered during the year. The principal oscillations that were recorded took place on the following days:—February 4-5, March 14-15, April 26, June 18-19, July 16, August 6-7 and 18, November 1-2.

Electrical Engineering in Switzerland.—Permission was granted by the Swiss Government authorities during last year for the establishment of 34 electric lighting plants (26 on the continuous-current system, and 8 on the alternate-current), 5 electric power transmission plants, 7 combined electric lighting and power transmission plants, and 1 electric tramway.

Municipal Electric Lighting in Berlin.—An important matter is just now under consideration in Berlin, nothing more nor less than the municipalisation of the electric lighting undertakings, a proposal having been brought forward at a recent meeting of the Municipal Council that the latter should acquire and carry on the various electric lighting stations of the Berlin Electricitatswerke.

Silver Jubilee of Eastern Telegraphy.—In connection with the 25th anniversary of the Eastern and Eastern Extension Companies, the employés of these Companies will present Sir John Pender with a massive silver centrepiece of emblematical design, in recognition of the services he has rendered to submarine telegraphy, and through it to the political, commercial and social life of the world, as well as of the warm interest he has always taken in the welfare of the staff.

Oil Insulation and Circulation.—The transformers at the power transmission plant of the Oerlikon Electrical Works are interesting from the fact of their having an oil circulation. Taking the average load on each transformer as 170 kilowatts, and allowing a loss in conversion of 2 per cent., some 3·4 kilowatts is being lost, appearing as heat. In order to dissipate this heat, the oil is circulated through serpentine tubes immersed in a tank through which there is a constant flow of cold water. The circulation is effected by means of a pump.

Postal Telegraph Clerks' Grievances.—Mr. Pickersgill, M.P., presided over a large meeting of the London telegraph staff, held in the Memorial Hall, Farringdon-street, on Wednesday evening, at which resolutions were passed unanimously protesting against the refusal of the Postmaster-General to redress the grievances of the postal telegraph service, and renewing their demand for a Parliamentary inquiry into the administration of the Post Office telegraphs. Telegrams of approval and encouragement were read to the meeting from the clerks in all the large offices throughout the kingdom. The speakers included, besides the chairman, Mr. W. Saunders, M.P.

Digitized by Google

Telegraph Messengers' Institute.—At the City Temple Schools last Thursday week the annual meeting and distribution of prizes of the East Central Postal District Telegraph Messengers' Institute was held. The number of members of the Institute was now estimated at about 500, and there is every prospect of a continued increase. The evening classes have been held on 55 evenings, 220 messengers joined, and the session showed a total attendance of 8,215. Mr. Spencer Walpole congratulated them on the Treasury having provided them with new premises, and expressed sympathy with the Institute. The report was adopted, and the prizes were distributed by Mrs. Sanderson.

Short Cuts to Knowledge.—In an interesting leading article on the dangers attending the increasing use of "short cuts" to knowledge by engineers, our esteemed contemporary, the *Engineer*, thus tersely expresses its views: "From a physical point of view, 'short cuts' proverbially lead the unwary and inexperienced traveller astray, land him often at a great distance from his wished-for goal, and prove, paradoxically as it may sound, the longest way to his destination. He has no alternative but to retrace his steps, and toilsome and arduous as this frequently is, it is but light labour in comparison with the strenuous efforts which attend a similar mental retrogression which becomes a task few can accomplish at any time, and after a certain age none."

Obituary.—We learn with regret of the decease in Berlin on 6th inst. of Imperial Privy Postal-Councillor Carl Grawinkel, whose name is well known in all matters relating to the German Telegraph Department. Originally stationed in Frankfort as telegraph engineer in that city, he was called some ten years ago to Berlin to become Dr. von Stephan's right-hand man in technical matters. He took a prominent part in the development of the telephone, and had several times visited London in connection with cable affairs. He was active in the telegraphic section of the Frankfort Exhibition in 1891. He was author of a German work on the Telephone, which ran through several editions, and had translated into German Prof. Silvanus Thompson's works on "Dynamo-electric Machinery" and on "The Electro-magnet." He was 49 years of age.

Electric Power for Gold Mining Purposes.—According to the Johannesburg correspondent of the *Glasgow Herald*, Mr. E. Lippert has formulated a scheme which contemplates the erection of an electric power station at Brakpan to deliver 2,000 effective horse-power at the mines. It is not intended at first to furnish battery power, but to supply motors for electric lighting and for various odds and ends both above and below ground. As the aggregate power used on the Rand is over 20,000 H.P., it will be seen that the scheme, by which it is hoped working costs will be considerably reduced, has not been formulated too soon. The firm of Siemens and Halske, of Berlin, are willing, it is reported, to lay down the plant and hand it over as a going concern upon receipt of 250,000 shares in a company with a nominal capital of £300,000.

Thunderstorms.—Several severe thunderstorms have occurred during the past week, and much damage to life and property has resulted. At Lowestoft the lightning struck the mast of a longshore fishing boat, killing two men and cutting a round hole in the side of the boat. At Glasgow a house was set on fire, it is said, though the ignition of gas by a lightning flash; and at Preston a servant girl was severely burned by the flames from a can of petroleum which had been set on fire in a similar manner. Even the stumpiness of a cricket wicket did not prevent the lightning splintering it to fragments, at the same town. The wicket was set up in the middle of a cricket ground, when the lightning struck it. Cattle, mostly under trees, have been killed and mutilated by lightning at a great number of places. The lightning struck a chimney at East Chiltington and cleaned off all the soot, making the brickwork look quite new.

Non-Magnetisable Watches.—The results of some interesting experiments, made by Capt. Wharton, the Hydrographer of the Admiralty, on the effect of powerful magnetic fields upon the going rate of non-magnetisable watches, have just reached us. The watches were of the well-known patterns, manufactured by Messrs. Smith and Son. They were placed at ½in. distance from the pole of a dynamo, which at the time was generating a current of 400 amperes at 80 volts, and which had a stray field which could easily be detected at 70ft. from the poles. At the end of a ten days' trial under these severe conditions it was found, curiously enough, that the watches kept better time than when they were not in any unusual magnetic field. The daily error during the ten days' trial never exceeded one second, and on four occasions was less than could be determined; while the daily error of the same watch, during a six days' trial under ordinary conditions, was never less than half a second, and attained a maximum of four seconds. In a similar trial of a different pattern of watch the results were practically the same.

Private Electric Lighting.—Electric engineers are often asked by the owners of large establishments to advise them whether it will be more economical to lay down their own lighting plant or to buy energy from a supply company. This, opines *Engineering*, is a difficult question to answer, seeing that the reply must be founded upon assumptions, many of which are more or less hypothetical. For example, the apparent cost of working a private installation depends greatly on the system of book-keeping adopted. A pedantic accountant will charge against the account every possible item he can think of. Not only will he include labour, coal, stores, interest, depreciation, rent and taxes, but also a share of his own salary, and of that of clerks, managers, foremen and watchman, and a proportion of the fire insurance. Another man will not only ignore these latter small matters, but he will also take no account of rent and taxes, on the ground that these have not been increased, nor the facilities of the establishment diminished, by the erection of the plant in an odd corner of the basement. Quite a sensible difference in the apparent cost per unit can be made by variations in the method of book-keeping.

The Pacific Cable.—At the Intercolonial Conference recently held at Ottawa, a resolution was adopted asking the Canadian Government, after the rising of the Conference, to make all necessary inquiries, and generally to take steps expedient, to ascertain the cost of a Pacific cable and promote the establishment of the undertaking in accordance with the views expressed by the Conference.——According to a Dalziel telegram, dated Montreal, July 10th, Mr. Alexander Siemens has submitted an offer to the Government of the Dominion of Canada for laying a cable under the Pacific ocean from Victoria, British Columbia, to Sydney, New South Wales. He undertakes to complete the construction within three years. His offer is now being considered. Reference was also made to this subject by Sir John Pender at the general meeting of the Eastern Telegraph Company, which was held yesterday, and is reported in our columns.——In reply to Sir G. Baden-Powell, Sir U. Kay-Shuttleworth stated in the House of Commons on Tuesday evening that soundings were taken by Her Majesty's ship "Egeria" during a period of about two and a-half years from 1888 to 1890 between the North Cape of New Zealand and the Phœnix Islands, about 200 miles south of the Equator; and the positions of several islands on that line were fixed and some were surveyed with a view to determining their suitability for cable stations. This was done in the ordinary course of hydrographic survey, in accordance with communications from the Admiralty to the Colonial Office. The distance between the extreme points of the area examined was over 2,000 miles.

Fatal Accident to a Voltmeter Boy.—A sad accident resulting in the death of a boy occurred at the British Insulated Wire Company's factory at Prescot last Friday. The youth, who was 19 years of age, was employed in the dynamo room as voltmeter boy and oiler, the station being in charge of a man who was superintending that and other machinery in the factory. The boy was alone in the engine-room at the time the accident occurred, and therefore the exact manner in which he met his death will never be known. He was seen alive at 9:20 a.m. in the engine-room and was found dead at 9:30 by one of the assistant electricians. The pressure at the time was 2,000 volts alternating, and on examination it was found that a voltmeter wire, which was well inside the frame and attached to one of the armature connections, had been forcibly broken at the soldered joint, and the end thus dragged away showed evident signs of burning. From the nature of the burns on

Digitized by Google

the boy's hands, and from the fact that he had a mark on the back of his neck, it is believed that he was leaning against a rail which runs parallel with the driving ropes, and stops short close up to the bed of the machine. While leaning against this rail he must either have slipped or fainted, and dropping between the end of the rail and the machine, his neck coming in contact with the ropes. While in this position he clutched at the armature of the machine, dragging out the voltmeter wire in question, and breaking it at the joint, so getting killed. The verdict at the inquest was "Accidental Death," and there was no suggestion of any negligence on the part of anyone concerned.

The Production of Hail.—A very interesting theory of the genesis, structure, and the metamorphosis of hail has recently been advanced by M. O. Marangoni. Heretofore the hailstone has been, to the popular mind, simply moisture that has been congealed in falling through strata of cold air; but its production is now shown to involve many processes. The hail cloud is first drawn out by the wind in a form of an horizontal tongue. It becomes rapidly evaporated, producing an intense cold. There are thus formed flakes of dry snow, which, by friction against the minute drops of water, become charged with negative electricity, and are then attracted by the positive electricity of the drops of water. The snowflakes behind the cloud—*i.e.*, to the windward—are covered with a layer of ice, at first dry and then moistened. Recent research has shown that they are at the same time charged with positive electricity, and are driven in an outward direction by the positive electricity of the rain drops. Being thus cooled below zero, they break through the cloudy stratum, and become charged anew with negative electricity, they are coated with a new snowy layer, and are again attracted by the cloud. Each hailstone, taking a wavy line, becomes enlarged by coating itself with alternate layers of opaque and transparent matter, and is ultimately thrown to the right or the left, occasioning thus the roaring noise which precedes the fall of hail, which then takes place in two parallel bands, separated from each other by a region of rain.

Oil Engine Trials at Cambridge.—The genuine and rapid progress which is being made by gas and oil engines was exemplified in the exhibits of these engines at the Royal Agricultural Society's Show at Cambridge recently. Most engineers have been awaiting with something akin to impatience the carrying-out of the careful scheme of oil engine trials which had been arranged, and are still anxious to hear the official results. It is some time since any independent trial of oil engines was made; and since then the older patterns have undergone considerable improvement, while many competitors have newly entered the field. There were 20 entries for the Cambridge examination, and the great majority put in an appearance. The judges had evidently an idea, remarks *Engineering*, that many of them had but little staying power, and that their labours might be lightened by putting a number of them out of court. Accordingly, they prescribed three days running at full load to commence with, the period being nominally 10 hours per day, but actually barely nine. During the whole of this period the engines were not to be opened up. so that the deposit (if any) might accumulate. If the judges had counted on a serious falling-off of numbers during this stage, they were disappointed, for only two engines failed to answer this test. These were the Root's engine of Clarke's Crank and Forge Company, and the "Capitaine" engine of Messrs. Tolch and Co., which we understand had not been previously tried with the prescribed oil—Russoline. This oil has a higher specific gravity and flashing point than the "tea rose" oil more generally used on account of its cheapness, and naturally an engine needs some adjustment in order to get the best results from it. At the end of the preliminary run of three days, during which, however, the brake load, revolutions, explosions, and oil consumption were regularly noted, came the more critical trials. These were a full-power trial of two hours, a half-power trial of two hours, and a light-running trial of four hours, during which all the data were carefully gathered.

Solar Disturbances and Terrestrial Magnetism.—In a Paper recently read before the Massachusetts Society of Arts, Mr. G. E. Hale remarks that the question as to the manner in which solar disturbances and terrestrial magnetic storms are related has long been under discussion, and its present condition is one of great uncertainty. The apparent existence of a twenty-seven-day period in the recurrence of magnetic perturbations is considered by some to indicate that disturbances in certain regions of the sun's disc—at the eastern limb or the central meridian, for instance—are alone capable of affecting the magnetic needle. To prove this it has been shown that the maxima of curves of magnetic intensity generally coincide with the appearance at the sun's central meridian of a spot or facula. Others have been no less successful in finding a spot or facula at the sun's eastern limb whenever an aurora is seen. The test whether these coincidences might not be due to chance, photographs of faculæ taken on 142 days in 1892 at the Kenwood Observatory were examined. It was found that for 1892 the probability that at any time one or more groups of faculæ would be on a given meridian of the sun was 0·93. Under such conditions it would be almost impossible for an aurora or magnetic storm to occur without the simultaneous existence of faculæ at either the central meridian or the eastern limb, and such coincidences must, therefore, be regarded as of doubtful importance. As for the *eruptions* photographed on the solar disc, that of July 15, 1892, was simultaneous with "slight trembling in the horizontal force magnet, which was the prelude to the violent storm which set in and lasted over the 16th and until midnight of the 17th." A similar though less important eruption shown on a spectroheliogram, taken June 20, 1892, was not accompanied by a disturbance of the magnets; but a series of small oscillations commenced one day later, and lasted until June 26th. Eruptions on January 26 and August 3 and 10, 1893, were without corresponding maxima on the magnetic curves. On August 6, 1893, there was a slight magnetic disturbance simultaneous with a small eruption.

Boiler Corrosion.—An abstract of a Paper from the German on "The Internal Rusting of Boiler Shells," has been published in the *Journal* of the Society of Chemical Industry. This report commences with an account of the physical and chemical phenomena which promote and cause the formation of rust upon iron. The internal rusting of boilers is dealt with under two headings, namely, when the boiler is in use and when it is standing idle. The causes of rusting are first considered, the most important being the introduction of air with the feed-water. By properly placing the feed-pipe—namely, so that the feed-water enters the boiler near the low-water level, and thus meets the hottest layers of water—the air is quickly expelled, and passes out of the boiler with the steam, unless pockets exist in which it can accumulate. Such pockets are sure to rust rapidly; and it is recommended that they should be covered internally with a protecting paint or filled up with cement, provided that they are not subjected to external heating. It is also recommended that the feeding should be completed before the withdrawal of steam ceases for the day, in order that the water left standing in the boiler overnight may be as free from air as possible. An efficient circulation is also a means of preventing rusting, as it hinders the formation of air bubbles on the shell, which, if they remain clinging to it, cause rusting. The author is of the opinion that faulty construction is more often the cause of internal rusting than unfavourable conditions of working, and summarises the means of preventing rusting as follows:—First, whilst the boiler is working—(1) Removing air from the feed-water before it enters the boiler. (2) Removing air from the water whilst in the boiler, and preventing its accumulation in pockets, &c. (3) Addition of chemicals to the feed-water. (4) Protective coatings applied to the inside of the shell. Second, whilst the boiler is standing idle—(1) Removing all moisture from the boiler, (*a*) by blowing it off whilst hot, (*b*) by producing an air current through it, (*c*) by placing hygroscopic bodies inside. (2) Direct protection of the shells, (*a*) by painting with tar, varnish, &c., (*b*) by covering with protective paints and such an alkaline coating as milk of lime. (3) Protecting the shells from varying temperatures by keeping the draught in the flues constant, and so as to prevent moisture alternately depositing and evaporating on the shell. (4) Protecting the shell by completely filling the boiler with water from which all air has been expelled.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(*Continued from page 176.*)

Furnaces and Boilers.

Green's Economiser.—Of appliances for utilising the heat of the furnace gases between the temperature at which the gases leave the boiler and the lowest temperature at which it is economical to allow them to enter the chimney, none is so well-known or has so largely been adopted in electric power stations as that manufactured by Messrs. E. Green and Son (Limited). Fig. 17 shows a longitudinal section of Green's economiser, with its setting, for about 400 to 450 H.P.—*i.e.*, for about 10,000lb. of feed water per hour. The economiser consists of a number of vertical cast-iron pipes, connected at the top and bottom by cross horizontal pipes in such a way as to give a multitubular passage for the feed-water. The water enters at the bottom right-hand main, D, and leaves at the top left-hand main, the former feed main having a blow-off connection, and the latter being fitted with a safety valve and thermometer. The group of pipes is suspended in an expansion of the flue between the boiler dampers and the chimney smoke-chamber, and the floor of this expanded flue is hollowed out to form a soot chamber, into which the soot, which is continuously scraped from the pipes, may fall. Scrapers are maintained in continual motion up and down the outsides of the vertical pipes for the purpose of keeping their surfaces efficient. These scrapers are suspended by chains, which pass over a number of toothed wheels above the roof of the economiser flue, and these wheels are rotated by a number of worm gears fitted on a shaft, which is driven from some convenient shafting or by a small engine or motor which can be attached to the end of the gearing frame. The direction of motion of these worm gears is automatically reversed at each time that the scrapers reach the end of the pipes. One of the most effective arrangements of an economiser, relatively to the boilers, which the author has met with is that shown in Fig. 18. The boilers, B B, discharge their furnace gases into a main flue. This flue is so arranged that the gases, before they reach the chimney, may be passed through the entire economiser or through only one-half of it; or they may be shunted through a reserve flue straight to the chimney. The whole arrangement is compact, and carries the gases through but a short length of flue; while in cases where the boiler plant is required to be a long time on light loads the advantage of using only half the economiser is very great.

An economiser of this description should not be supplied with quite cold water, otherwise the pipes and bottom boxes become chilled and condensation of the vaporous gases ensues, thus causing a deposit of mixed soot and water to adhere to their outer surfaces, and this deposit hardens on the pipes and cannot be thoroughly removed by the scrapers. An even more important point, however, is the rapid corrosion which takes place, unless the feed water is slightly warmed before entering the apparatus. Moreover, a hot-feed into the economiser will prevent the pipes being choked with mineral deposits. The usual allowance of heating surface in a Green's economiser is four 10ft. pipes per ton of fuel burned per week; or, where the consumption of fuel is not easily predetermined, one pipe for every three I.H.P. gives about the same result. These data are based upon an assumed feed-temperature of 90°F., the lowest temperature at which it is advisable to feed the water into this type of economiser. The proportion of economiser surface to the useful surface of the boiler flues varies from 0·6 to 1·0. From the data supplied by Table XV., the saving in fuel by the use of an economiser may be estimated, as compared with the performance of the same boiler plant without the economiser.

Feed Pumping.—The work done in pumping water into the boilers is by no means an insignificant item of the load on the engine or boiler plant. This work may be divided into two parts: (1) raising the cold water to the level of the boilers, and (2) forcing the water into the boilers against the back pressure of the steam. The sources of feed water have already been enumerated; and it will be seen that in some of these the water would require considerable work to be done in raising it to the feeding level. In many stations the cost of town water is so great that it is less expensive to pump water, both for boiler feed and for condensing purposes, from well borings, or to raise the dirty water of a neighbouring river up to a filter tank, whence it would descend to the boiler feed pumps. In non-condensing stations the exhaust steam cannot be recovered, and a continual draught has to be made upon the lifting pumps for feed water, in proportion to the total evaporation of the boiler plant; but in condensing stations most of the feed water circulates continuously between the boilers and the cooling pond or tanks, and has only to be supplemented by new water in proportion to the loss by evaporation and leakage.* A "feed make-up evaporator" is a

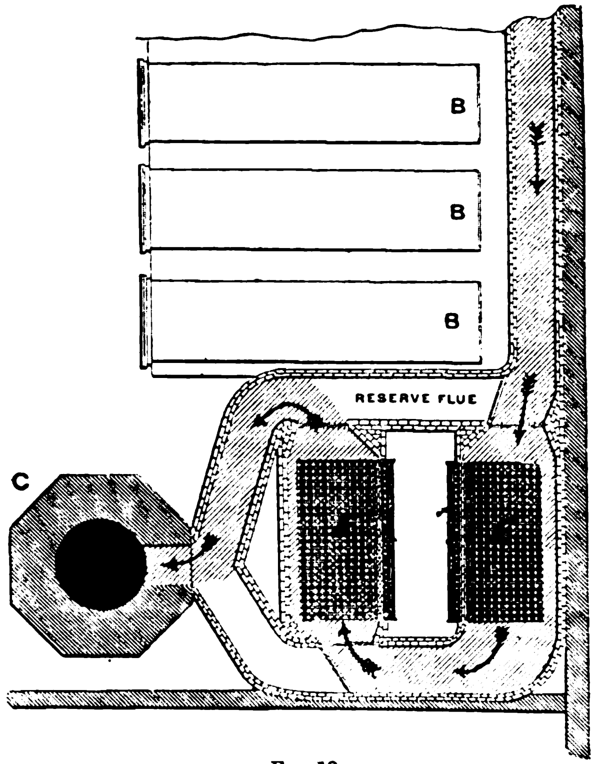

Fig. 18.

supplementary evaporator for supplying this additional water where surface condensers are used, the water from the source being unsuitable for direct feed into the boilers.

Whether the station is non-condensing or condensing will not directly affect the fact that work must be done in pumping the feed water into the boilers; although in the latter case, since less water will be required, less work will have to be done. Theoretically, the work may be estimated from the volume of water fed, in cubic ft., and the effective pressure of the steam; and, if Q is the number of cubic ft. fed per minute, and p the effective back pressure of the steam in lbs. per sq. in., the theoretical H.P. expended will be:—

$$\text{H.P.} = \frac{144\,Q\,p}{33{,}000} = 0.00436\,Q\,p \quad . \quad . \quad . \quad . \quad (83)$$

In practice, the effective H.P. is from ten to fifty per cent. greater than this, exclusive of power absorbed in the pump, owing to frictional losses and shocks. The allowance of effective H.P. must be still greater, because it will sometimes be necessary to feed the boilers much above the normal rate and because there is a certainty of the pumping machinery being sometimes under repair. Where there are two feed pumps, it is usual to provide that each one shall be capable of feeding the boilers at or slightly above the normal rate; where there are more, there should always be at least one as a reserve; or where there are two sets of boilers (as at some stations) each fed from a distinct set of feed pumps, there should be a reserve pump at each set. A portion of the reserve pumping apparatus often takes the shape of a live-steam injector.

* An exception occurs in the few cases where, as at the Portsmouth Corporation electric supply station, jet condensers are used with condensing water which is too foul to be fed into the boilers. In such cases all the heat of the exhaust, as well as all of the boiler water, must pass away with the water from the condensers. It is difficult to understand the circumstances which could lead an engineer to prefer or adopt such a system as this.

"Worthington" Steam Feed-Pump.—Direct-thrust steam feed-pumps, such as those manufactured by the Worthington Pumping Engine Company, are very largely used in electric power stations for feeding boilers. Direct-thrust cannot conveniently be combined with low steam consumption, owing to the difficulties in using the steam expansively; but the simplicity of construction and the consequent small liability to get out of order have led to the almost general adoption of this type of feed pump. Considerable saving in labour is effected by making the feeding plant automatic in its action. The exhaust steam from the feed pumps should be passed through the feed heaters, as thereby some of its heat is recovered and the efficiency of the pumping plant is increased.

Typical Boilers.

"Robey" Lancashire Boiler.—Some account will now be given of some typical electric power station boilers. No attempt will be made to describe the design of these in regard to rules affecting the strength, but only in regard to the performance and efficiency of the boilers. Commencing with the Lancashire type, we may take the "Robey" boiler, manufactured by Messrs. Robey and Co., as being an example which departs only in a few minor details from standard practice and proportions. In this boiler the length of shell is 28ft., a length not often exceeded in electric power stations, though some stations have 30ft. boilers, and the diameter of the shell is 7ft., which for high pressures is a very safe figure, though where lower pressures of steam are used the diameter often reaches 8ft. 6in. There are six "Galloway" cross tubes in each of the two internal flues. Many makers, however, prefer to fit only three or four of these tubes into each flue. Each grate has an area of 19 sq. ft., making a total grate area of 38 sq. ft. At the ordinary rate of steaming, this boiler will evaporate 5,400lb. of water (hot feed) per hour; but the steaming rate may easily be raised to 6,000lb. per hour without distressing the boiler. Running a compound engine, this boiler will develop 240 I.H.P. at its ordinary rate of working. The consumption of good coal, at ordinary load, would be about 650lb. per hour, or at the rate of about 17lb. or 18lb. per square foot of grate per hour. The normal steam pressure on the gauge is 120lb. per square inch. The allowance of heating surface for this boiler is 750 sq. ft., which is somewhat under the usual allowance. The heating surface consists of 360 sq. ft. of internal flue surface, and 390 sq. ft., of external flue surface. The ratio of the heating surface to the grate area is practically 20. The normal evaporation per square foot of heating surface per hour is 7·2lb., which is a very high rate, and one which could only be obtained under normal conditions with well-heated feed water. When forced, this boiler will evaporate 8lb. of hot feed water per square foot per hour. After passing through the two internal flues, the furnace gases descend to the external flue directly below the boiler, passing to the front along this flue. At the front, they divide into two halves, and pass along two side flues. Again reaching the back of the boiler, the gases mingle and pass on to the economiser and chimney. Most makers of Lancashire boilers now adopt this mode of setting, in preference to the older plan of carrying the gases through the side flues before passing them through the bottom flue. The new plan has the advantage that better circulation is promoted, because hotter gases are brought into contact with the very bottom of the shell.

The feed water inlet-pipe is placed directly below the water line, the water entering at the front end of the boiler, through a feed stop-valve fixed to the front plate. The water traverses

Digitized by Google

about 15ft. of inlet-pipe before dispersion; and with cold feed, or only moderately hot feed, this provides for the water becoming heated before it is dispersed into the boiler. Otherwise, the water might fall to the bottom of the shell and cause shrinkage through cooling the plates. Dispersion is produced by a perforated length of inlet-pipe. Where the feed-water is at the evaporating temperature on its entering the boiler, so great a length of inlet-pipe is not necessary, and feed may take place directly into the dispersion pipe. In such a case the inlet must be at the back of the boiler. The advantages of feeding just below the water line are: (1) that with cold or slightly warm feed a better circulation is promoted, and (2) that in any case the risk of the boiler becoming emptied and the crown of the furnace being exposed, by any mishap to the feed check valve, is removed. Boilers fed at the bottom of the shell have exploded through becoming emptied while under fire, the water having been forced by the steam pressure out of the shell *viâ* a defective check valve. In this connection, we may refer to the Hopkinson low-water safety valve, which is fitted on the boiler. In its usual form, this fitting gives warning both of too high a pressure of steam and of too low a water level. In some boilers, this fitting is arranged to open a communication between the boiler and the auxiliary feed connections.

Below the mounting for the steam stop valve is fitted a steam collecting pipe, consisting of a horizontal perforated cylinder supported on end brackets. The purpose of this collecting pipe is the separation of primed water from the steam. Where the connections of steam mains to the boilers are duplicated, it is sometimes the practice to have two separate mountings or stand-pipes, both connected to the same collecting pipe. More commonly, there is a single mounting connected to a steam drum or to a U-pipe with two stop valves.

The passage way for the furnace gases in this type of boiler is usually proportioned as follows:—

Position of flue.	Percentage of area of grate.
Air space in grate	33·0
Space over bridge	12·0
Internal flue between cross tubes	36·0
Bottom external flue	22·0
Side flues (each)	20·0
Side flues (total)	40·0

In the Lancashire boiler about 43 per cent. of the heating surface is usually contributed by the internal flues, 8·5 per cent. by the cross-tubes in these flues, and the remaining 54·5 per cent. by the external flues. The total heating surface varies directly as the product of the length into the diameter of the shell; the water capacity and steam space varying directly as the product of the length into the square of the diameter of the shell. Of the heating surface, only about 10 per cent. is exposed to direct radiation from the solid fuel on the grate; and even this proportion is not attained except by the use of long grates. It is of the utmost importance, therefore, that flame radiation shall be provided; in other words, this type of boiler is not adapted to the combustion of dry fuels, such as anthracite, Welsh coal or coke, but its performance and efficiency may be very high—as high as those of any other boiler—when suitably bituminous or flame-producing coal is burned on its grates.

(To be continued.)

ON IMPULSIVE CURRENT-RUSHES IN INDUCTIVE CIRCUITS.

BY ALFRED HAY, B.SC. (EDIN.)

(Continued from page 262.)

§ 11. Before dismissing the subject of current-rushes in circuits of constant permeability, it may be well to point out the effect on the current-rush of varying the periodicity. Referring once more to equation 3 of § 4, we see that if the value of t in the term $e^{\frac{-rt}{L}} \sin\theta$ on the right-hand side is considerable, this term becomes very small. Also, since $\tan\theta = Lp/r$, it follows that a lowering of the periodicity will have the effect of diminishing θ, and therefore also $\sin\theta$.

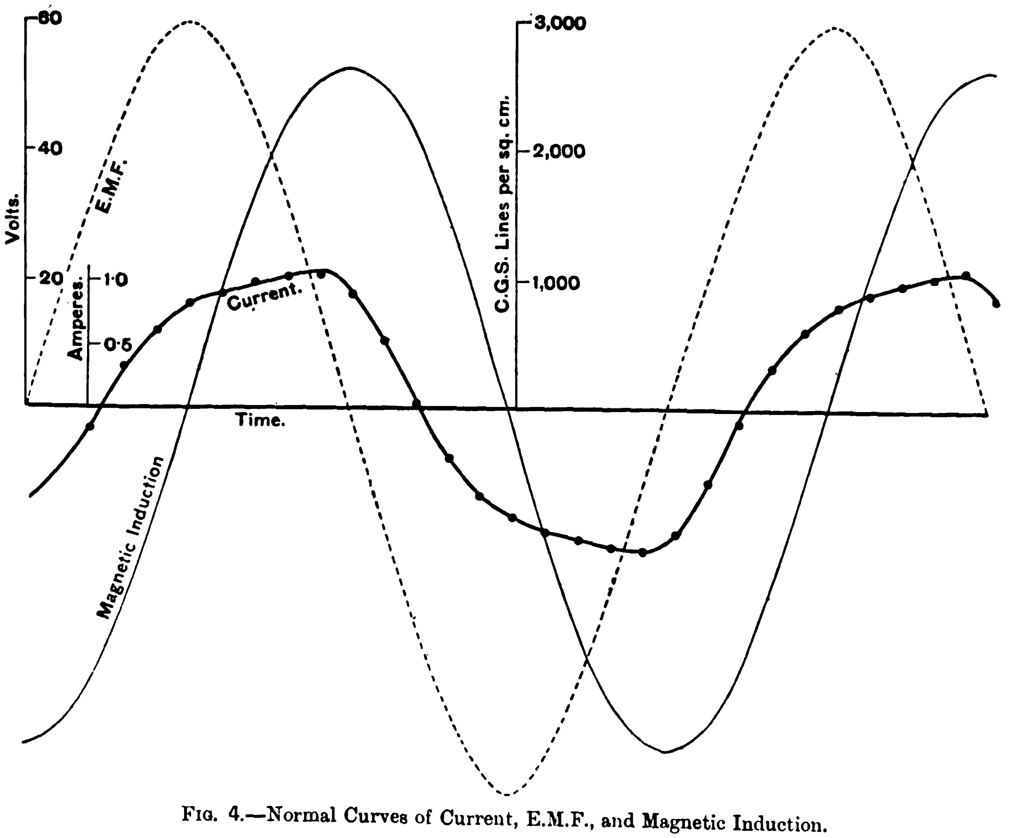

Fig. 4.—Normal Curves of Current, E.M.F., and Magnetic Induction.

Digitized by Google

Now it is evident that with a lower periodicity, a wave, whether normal or abnormal, takes a longer time to rise to its crest. Hence, if the periodicity is lowered, the value of t corresponding to the crest of the wave is increased, and the

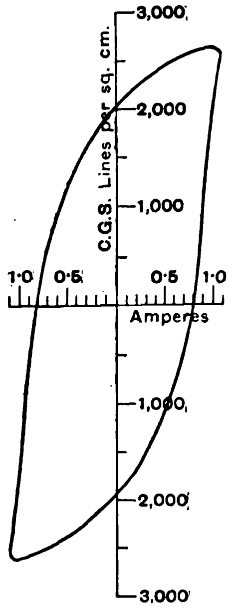

Fig. 5.—Normal Hysteresis Loop.

value of $\sin \theta$ is diminished. Both these causes will reduce the distortion of the waves. We thus have the result that *the current-rush increases with the periodicity.*

Experiments on Current-Rushes in Inductive Circuits containing Iron.

§ **12.** We have now to investigate the much more difficult problem of impulsive current-rushes in circuits whose inductance is not constant, and which are further complicated by

1. The phase of the E.M.F. at the instant of switching on; 2. The initial magnetic state of the iron, determined by the phase of the E.M.F. at the instant of breaking the circuit; 3. The normal maximum of magnetic induction at which the iron is worked.

§ **13.** The transformer used in the experiments described below was specially constructed for experimental purposes. The core was built up of 245 discs of annealed soft iron, each ·0123in. thick, having an external diameter of 8in. and an internal diameter of 5in. The mean length of the magnetic circuit was thus 51·9 cm., and its sectional area 29·2 sq. cm. The discs were insulated from each other by a coating of bitumen varnish. The winding consisted of three sets of coils, each wound with cotton-covered copper wire ·083in. diameter; we shall call these coils A, B and C respectively. Each coil was subdivided into 12 sections; every section of coil A contained 48 turns, so that the total number of turns in coil A amounted to $48 \times 12 = 576$. Coils B and C had eight turns in each section, giving $8 \times 12 = 96$ turns for each coil. The various sections of each coil could be connected up in different ways, and any section of any one coil coupled to any section of any other coil.

§ **14.** In order to compare the normal working condition of the transformer with the changes which take place during a rush, it became necessary to obtain the normal E.M.F. and current curves of the tranformer when working on open secondary circuit. These curves are given in Fig. 4. The periodicity was 122 ∿ per second. Coil B (of 96 turns) was used as the magnetising coil. The resistance of this coil was 0·21 ohm, and the non-inductive resistance connected in series with it was 0·809 ohm, giving a total resistance of about 1·02 ohm. By subtracting from the ordinates of the E.M.F. curve the drop due to resistance of the circuit, we obtain the counter-E.M.F. curve of the transformer. By integrating this latter we find the curve of magnetic induction, after the manner used by Dr. J. Hopkinson in his experiments on magnetic viscosity (see *The Electrician*, Vol. XXIX., p. 510). If b stand for the instan-

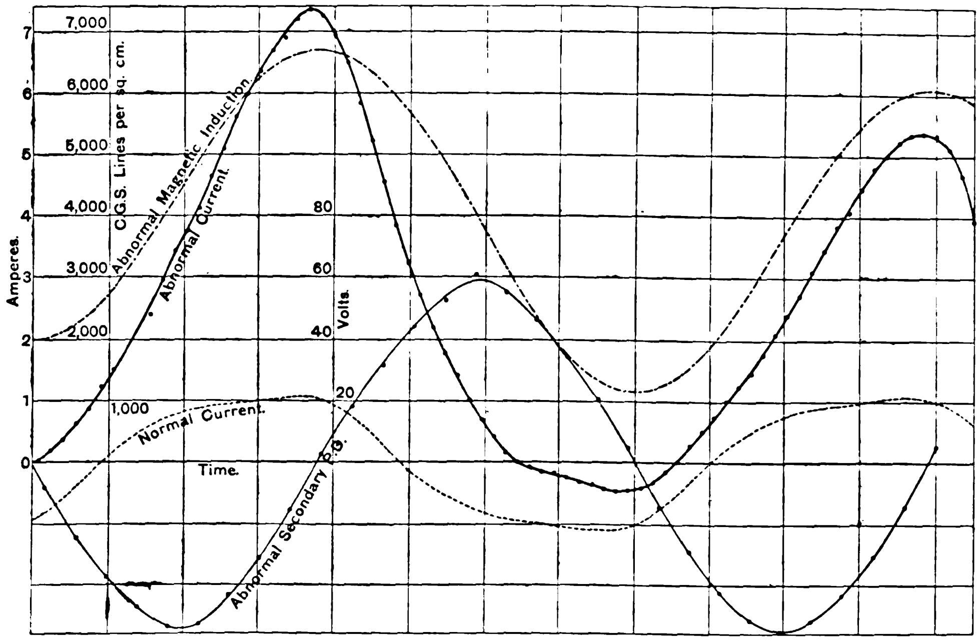

Fig. 6.—Abnormal Curves of Current, E.M.F., and Magnetic Induction.

the phenomenon of hysteresis. Without at present going into theoretical considerations as to what might be expected to take place in such cases, we at once proceed to give the results of experiments showing what actually does happen.

In dealing with circuits immersed in a medium of constant permeability, it was unnecessary to note the phase of the current at the instant of switching off. In the present case, however, we must take into account the initial magnetic state of the iron, and this, as is shown by experiment, plays an important part in determining the current-rush. The main factors to be considered in dealing with this problem are:—

taneous magnetic induction (in C.G.S. lines per square centimetre), a for the sectional area of iron (in square centimetres), and S for the number of turns in the magnetising coil, then, e denoting the instantaneous counter-E.M.F. in volts, we have

$$e = \frac{a\,S}{10^8}\,\frac{d\,b}{d\,t},$$

whence

$$b = \frac{10^8}{a\,S}\int e\,d\,t + \text{constant},$$

the constant being determined by the consideration that the maxima and minima of the integrated curve correspond to equal mag-

Digitized by Google

netisations of the core in opposite directions. In our experiment, $a = 29 \cdot 2$ sq. cm., S = 96, so that $b = 35{,}700 \int e\,d\,t +$ constant. The integrated curve is shown in Fig. 4. We can now draw the hysteresis loop for the iron by taking corresponding values of the current and magnetic induction. This loop is shown in Fig. 5. The scale of current may be converted into a scale of magnetic force by multiplying by a certain constant. Since the number of turns in the magnetising coil is 96, the magnetomotive force is $\frac{4\pi}{10} \times 96\,i$ (where i stands for the current in amperes) or $120 \cdot 7\,i$ approximately. Dividing this by the mean length of the magnetic circuit, viz., 51·9 cm., we obtain $2 \cdot 32\,i$ for the magnetic force. Multiplication by the factor 2·32 therefore converts the current scale into a scale of magnetic force. The greatest value of the induction is about 2,630 C.G.S. lines per square centimetre. The corresponding value of the current is 1·09, and of the magnetic force $1 \cdot 09 \times 2 \cdot 32 = 2 \cdot 53$. We thus get for the permeability corresponding to this induction $\frac{2{,}630}{2 \cdot 53} = 1{,}040$ approximately (this agrees very fairly with the result obtained by Ewing for a certain specimen of soft iron. *See* his "Magnetic Induction in Iron and other Metals," p. 55.)

§ 15. We may now compare the normal current curve with the curve during a rush. With precisely the same arrangement of the circuit as that used in obtaining the normal curve, we get an enormous distortion of the initial current waves, as is evident from Fig. 6. During the first half-wave the current runs up to about 7·35 amperes, and since the normal maximum is 1·09 amperes, the current rush (§ 3) is $\frac{7 \cdot 35}{1 \cdot 09} = 6 \cdot 74$. The abnormally large half-wave is succeeded by an abnormally small one (just as in the case of a circuit of constant permeability); this, again, is followed by an abnormally large half-wave, and so on. For the sake of comparison the normal current wave is repeated in Fig. 6 in dotted lines. In order to determine the changes which the magnetic induction undergoes during a rush, a set of readings was taken for the secondary potential difference curve (coil C, which had the same number of turns as the magnetising coil B, being used as the secondary). This secondary potential difference curve is also given in Fig. 6. It will be noticed that, as might have been expected, it is considerably distorted. By integrating this curve we obtain the magnetic induction curve, which is the chain-dotted curve of Fig. 6. The rush shown in Fig. 6 is the greatest rush which it was possible to obtain when working at the given magnetic induction.

(To be continued.)

PHOTO-ELECTRIC RESEARCHES OF M. AUGUSTE RIGHI.*

BY DR. OLIVER LODGE.

M. Righi has observed the following facts: (1) That ultra-violet rays reduce to sensibly the same potential two metals placed near each other (plate and gauze parallel and close); (2) That several photo-electric couples of this kind can form a battery; (3) That a simple metallic plate charges itself positively under the influence of radiation; (4) That a voltaic arc formed with a zinc rod gives the strongest effect, while the sun gives none.

Besides these facts he finds:—(*a*) That certain gases and vapours, such as coal-gas and CS_2, absorb the active rays strongly.

(*b*) That if the discharging body is easily movable it recedes like an electric windmill.

(*c*) A film of gypsum interposed between gauze and plate charges itself negatively on the side facing the negatively-charged plate.

(*d*) Radiation produces its discharging effect even on non-conductors (ebonite and sulphur). With glass, resin and varnishes the action is feeble, or nearly nothing.

* *Comptes Rendus*, vol. 107, p. 559.

(*e*) If the experiment is made with a copper gauze and a zinc plate, the phenomenon nearly disappears on varnishing the gauze. His hypothesis is that radiation produces convection of negative electricity, the carriers being molecules of air.

(*f*) The carrying molecules move along the lines of force, and throw electric shadows. To show this he varnishes a zinc cylinder, all except a generating line, charges it negatively to 1,000 volts with a dry pile, and places it parallel to a large earth-connected plane, which has a narrow rectangular portion insulated from the rest and communicating with an electrometer. Light only acts on the uncovered line of the cylinder, and on turning the cylinder round the electrometer is only deflected when it is exposed to some of the (circular) lines of force emanating from the active line of the cylinder.

(*g*) Radiation charges positively an insulated metal, even when it is an enclosure with walls of the same metal: the metal being certainly uncharged at the beginning of the experiment. The same occurs with sulphur and ebonite. If there is a feeble initial *plus* charge, radiation increases it.

(*h*) While the discharging power of radiation for negative electricity is strongest with zinc and aluminium, and slower with copper and gold, following the Volta series; the E.M.F. set up by radiation, when it charges things positively, is greatest with gold and carbon, and less with zinc and aluminium; again following the Volta series, but inversely.

(*i*) If radiation falls on an insulated metal plate connected with an electrometer, in an enclosure of the same metal, the positive electrification shown by the deflection of the electrometer is greater as the plate is further from the walls of the enclosure. The action stops when the metal has attained a certain electric density, constant for a given metal; so the potential of a plate is naturally higher as its capacity is less. It is thus established that radiation acts on the particles of gas in contact with a conductor; they go away with a negative charge, leaving *plus* on the conductor, until an electric density sufficient to balance this action is attained.

(*j*) It is probable that if the solar rays do not produce an effect it is because of the absorbing action of the atmosphere. In fact, if one places a tube whose ends are glazed with selenite between the source of light and the metals being experimented on, the effects become sensibly stronger when the tube is exhausted.

THE ROTATION OF THE ELECTRIC ARC.*

BY A. P. TROTTER.

In the course of experiments made with the view of realising as a practical standard of light, the method of using one square millimetre or other definite area of the crater of the positive carbon of an electric arc†, the author has found that the effective luminosity is not as theory would predict,‡ either constant or uniform. By the use of a double Rumford photometer, giving alternating fields, as in a Vernon Harcourt photometer, his attention was called to a bright spot at or near the middle of the crater. The use of rotating sectors accidentally revealed that a periodic phenomenon accompanied the appearance of this bright spot, and although it is more marked with a short humming arc, the author believes that it is always present.

An image of the crater was thrown on a screen by a photographic lens; and a disc having 60 arms and 60 openings of 3°, and rotating at from 100 to 400 revolutions per minute, was placed near the screen. Curious stroboscopic images were observed, indicating a continually varying periodicity seldom higher than 450 per second, most frequently about 100, difficult to distinguish below 50 per second, and becoming with a long arc a mere flicker. The period seemed to correspond with the musical hum of the arc, which generally breaks into a hiss at a note a little beyond 450 per second. The hum is audible in a telephone in the circuit, or in shunt to it. The current was taken from the mains of the Kensington and Knightsbridge Electric Light Company, often late at night, after all the dynamos had been shut down. The carbons were, of course, not cored; six kinds were used.

A rotating disc was arranged near the lens, to allow the beam to pass for about 1/100th of a second, and to be cut off for about

* Paper read before the Royal Society.

† J. Swinburne and S. P. Thompson, discussion on Paper by the Author, "Inst. Electrical Eng.," Vol. XXI., pp. 384 and 403.

Digitized by Google

1/100th of a second. It was then found that a bright patch, occupying about one quarter of the crater, appeared to be rapidly revolving. Examination of the shape of this patch showed that it consisted of the bright spot already mentioned, and of a curved appendage which swept round, sometimes changing the direction of its rotation. This appendage seemed to be approximately equivalent to a quadrant sheared concentrically through 90°. Distinct variations in the luminosity of the crater are probably due to the fact that this is only an approximation.

The *a priori* theory of the constant temperature of the crater is so attractive, that the author is inclined to attribute this phenomenon, not to any actual change of the luminosity of the crater, or to any wandering of the luminous area, as is seen with a long, unsteady arc, but to the refraction of the light by heated vapour. All experiments, such as enclosing the arc in a small chamber of transparent mica, or the use of magnets, or an air blast, have failed to produce any effect. A distortion of the image of the crater while the patch revolves, has been looked for, but nothing distinguishable from changes of luminosity has been seen.

An unexpected difficulty is thus introduced in the use of the arc as a standard of light, and one which may interfere with its use under some circumstances as a steady and continuous source of light. The author is further examining this phenomenon with the view of ascertaining its nature, and of finding practical conditions under which it is absent or negligible.

NOTE ON THE POSSIBILITY OF OBTAINING A UNIDIRECTIONAL CURRENT TO EARTH FROM THE MAINS OF AN ALTERNATING CURRENT SYSTEM.*

BY MAJOR P. CARDEW.

In carrying out some tests on the high-pressure alternating current system of the Metropolitan Electric Supply Company (Limited), of a combination intended to act as an indicator of leakage to earth, the existence under certain conditions of an excess of current in one direction to earth by leakage through the dielectric of the cables, or through small faults therein, has been demonstrated. The combinations and connections used are shown in Fig. 1, where A is the alternating current generator, M_1 and M_2 the distributing mains, T T the transformers, B a battery of a few

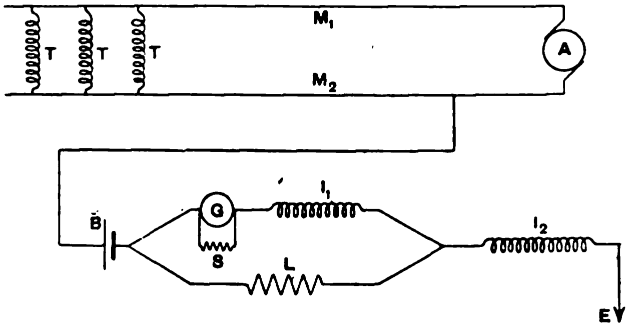

Fig. 1.

Leclanché cells, G a sensitive D'Arsonval reflecting galvanometer, S its $\frac{1}{9}$ shunt, I_1 and I_2 impedance coils, calculated to pass a current of less than 0·005 ampere with the whole alternating pressure in use on the system between the terminals; L a non-inductive resistance formed of four 50-c.p. 50-volt incandescent lamps in parallel, E a connection to the iron water-pipes supplying the station.

The object sought to be attained by the use of this arrangement was to obtain an indication of any leakage on the alternating system by a method which would be unaffected by the capacity effect of a large system. It is intended to substitute for the D'Arsonval galvanometer used in these tests a form of siphon recorder, so as to obtain a continuous record of leakage.

In the first test, made on April 25, 1894, the mains in connection consisted of eleven circuits all connected to one machine. The pressure in the alternating circuit was rather greater than 1,000 volts, and about half this pressure was indicated by an electrostatic voltmeter between M_2 and earth throughout the experiments. The battery used was six cells, and the following deflections were obtained :—

With +ve pole of battery to the mains...... 20 to left.
With −ve ,, ,, ,, ... 140 to right.
With battery out of circuit .... 48 ,,

Various modifications were tried ; but in all cases the results showed an apparent electromotive force of from 5 to 6 volts, tending to cause a flow of positive electricity to the water-pipe earth.

* Paper read before the Royal Society.

In order to settle this question, a small copper voltameter, consisting of two No. 40 S.W.G. copper wires in $CuSO_4$ solution, was inserted in place of the galvanometer and the shunts were removed. In two hours and ten minutes after connection the wire connected to the mains was so far eaten through that it dropped off, while that connected to the water-pipe earth was visibly thickened by a deposit of copper. The gauge of the wires before and after this experiment was approximately as follows : Original gauge of each, 0·005in. ; gauge of anode after experiment, 0·002in. ; ditto of cathode, 0·0069in.

The connections are shown in Fig. 2, where V is the voltameter cell, *a* the wire which acted as anode, *k* that which acted as cathode.

On May 2, 1894, some further tests were taken. In the first place a connection to the opposite main was substituted for the connection to the water-pipe, as shown in Fig. 3. This connection gave a deflection of about 235 to either side, according to the direction of the battery E.M.F., and absolutely no deflection without the battery. On reverting to the connections of Fig. 1, a deflection of 130, gradually falling to 98 in 10 minutes, was ob-

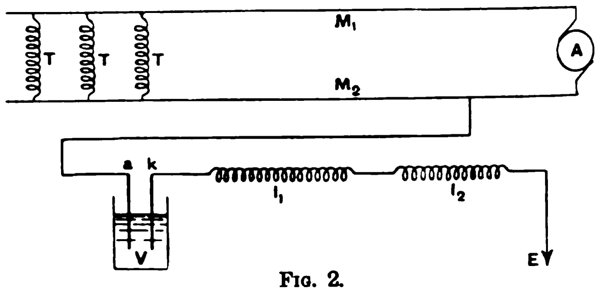

Fig. 2.

tained without any battery ; and five Leclanché cells connected +ve to mains exactly reduced the deflection to zero. The deflections obtainable with the connections of Fig. 1 without battery for varying lengths of street mains in connection with the machine were then found to be as follows.

With the trunk main to Manchester Square Station alone, disconnected at the far end, no deflection was obtained :—

Adding No. 10 circuit, deflection of 15
,, No. 11 ,, ,, 25
(with a sudden rise to 70 and then a fall to 20).
Adding No. 12, no increase of deflection
(this is a small circuit for station lighting only).
Adding No. 7 circuit, deflection of 35
,, No. 6 ,, ,, 40
,, No. 5 ,, ,, 48
,, No. 4 ,, ,, 63
,, No. 3 ,, ,, 70
,, No. 2 ,, ,, 90
,, No. 1 ,, ,, 115

In all cases the first deflection was a few scale divisions greater than that after a few minutes.

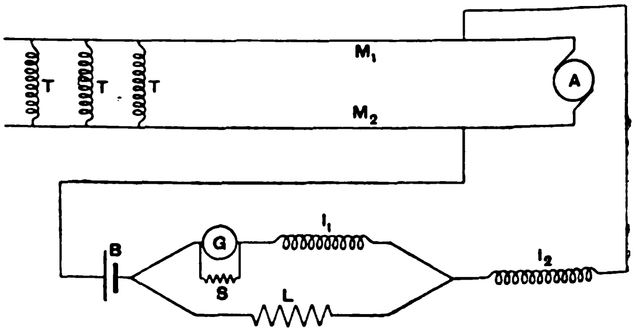

Fig. 3.

The effect of an artificial leak of about 103,360 ohms resistance, consisting of a pencil of graphite mixed with clay or cement, and connected to the water pipes and to the main M_1, was then tried. This produced no effect on the deflections without a battery, but slightly increased the deflection with a battery and with all mains connected. When tried on the trunk main alone with the lamps removed, galvanometer unshunted, and six Leclanché cells, the deflection was increased from about 23 to 360. With seven Leclanché cells (say 10 volts) and the impedance coils and shunts as shown in Fig. 1, a deflection of four scale divisions was produced when the circuit was completed through the resistance of 103,360 ohms in place of the mains and earth ; this gives an indication of the sensibility of the arrangement.

Digitized by Google

The explanation of the results obtained appears to be that when the cables are charged with positive electricity the polarisation produced is sufficient during the time of one alternation to considerably increase the resistance of the slight leakage to earth by the formation, probably, of a film of oxides; this obstruction is cleared off by the succeeding wave of negative charge, which, as is well understood, opens the leak. The time of an alternation is, however, quite insufficient to produce any such effect on the water-pipe earth, and, in consequence, the net result is a passage of negative electricity to earth through the cables, and of the corresponding positive quantity to earth by the water-pipes.

The maximum effect that has been observed so far amounts to an apparent E.M.F. slightly exceeding 10 volts, with the eleven circuits connected to one machine; but it appears that a greater effect would be produced by still further increasing the length of mains in connection.

HEINRICH HERTZ.*

(Continued from page 274.)

In 1881 we already find him investigating electrical equations which do not belong to the older theories. An interesting Paper written at this time is "On the Distribution of Electricity on the Surface of Bodies in Motion." The theory of action-at-a-distance shows that in every electrically-charged body at rest the charge resides wholly on the surface, so that the interior of a hollow sphere is quite free from any trace of the hypothetical fluid, and throughout the whole conductor the electric potential has everywhere the same value, even in the interior of the mass of the conductor. Hertz asks himself, "What happens if bodies so charged are moved towards each other?" The distribution of electricity on the surface must at any instant be quite different from that on the surface of bodies at rest, even if these could be brought to exactly the same position in space as the moving conductor momentarily occupies; further, the potential is now no longer constant, either on the surface or in the interior of the body, and whereas a hollow metallic conductor at rest completely screens its interior from external electrical forces, this is no longer the case when the conductor is in motion. Currents are set up in its interior, and along with them heat is developed, resulting in an apparent loss of energy. Continuous motion of charged bodies can therefore only be kept up by supplying external work.

Hertz developed very skilfully the formulæ for these cases, and the general formulæ of electrostatics are greatly extended by them. He applied the general solutions to the specially important cases of a solid of revolution rotating in an electric field with constant velocity about an axis, and particularly considered solid and hollow spheres and cylinders. In the latter, even in a uniform field, electric currents are set up which are deflected in a singular fashion by the rotatory motion; inductive effects act through the metallic body upon its interior, so that it no longer behaves as a perfect screen, and so on. In connection with this Hertz arranged an experiment. Over a horizontal and only moderately good-conducting glass plate a needle, provided at its ends with horizontal metallic plates, is suspended by a metal wire. As soon as these plates are charged so that they become electric poles their oscillation becomes greatly damped. The phenomenon is analogous to the damping of a swinging magnetic needle which excites opposing induction currrents in a copper conductor surrounding it. In this work we find the following significant passage:—"If an electric pole be moved at a constant distance above a flat plate the electrification, when once excited, follows it, and the simplest and, indeed, the usual explanation is that the electricity, supposed material, is the thing which moves, but we reject this hypothesis." We here see Hertz already freeing himself from the "usual explanations."

In the year 1883 he devoted his attention to a group of phenomena which always interested him, namely, electrical discharges in gases. In his first work on this subject, "On a Phenomenon accompanying Electric Discharge," he describes some singular luminous rays and cloud-like or arborescent appearances observed when the electrical discharge from an induction coil is allowed to pass out of a tube into a mass of gas which is not too highly rarefied; the positive electrode was inside the tube and the negative one near its mouth. The experiments were greatly varied, and the description of them, although only eight pages long, is full of detail.

To the same year belong the "Researches on the Glow-Discharge," which were carried out in Berlin, although the Paper is dated from Kiel. At that time there existed but three methods for the production and study of the phenomena of electric discharges as they occur in rarefied gases; namely, the influence machine, the induction coil and large voltaic cells of high electromotive force. Of these Hertz chose the third, and constructed a secondary battery with 1,000 pairs of lead plates, enabling him to obtain an electromotive force equal to that of 1,800 Daniell cells in series. The current yielded by it was led by electrodes into discharge-vessels of various shapes. Hertz observed more especially the luminous appearances near the cathode with high vacua.

Here it is the rays of the glow-discharge and the cathode rays, which are certainly related to them, concerning which Hertz's work discloses many important facts, although he was not able to entirely lift the veil from them. Apparently this was not possible except from his higher point of view attained through the later researches, namely, that of the doctrine of electric oscillations and waves. Even here we find occasional mention of electrical waves and of electrical movements which are propagated through a medium like waves; but the ideas are not yet so clear as they came to be eventually by reason of the later striking experiments.

The first part of the Paper is devoted to an old and much-debated question, "Are the discharges through a rarefied gas continuous or discontinuous? Are they still discontinuous in the particular case considered here, when we apply to the gas an apparently continuous battery current?"

Hertz endeavours by ingenious arrangements to prove that his discharges are continuous. On looking over the lines of the argument, however, it is seen that they are only able to establish a lower limit to the number of separate discharges in a second. Whether discontinuities of very high frequency occur or not cannot be definitely decided by the method used, a fact of which Hertz himself was quite aware. If we consider the phenomena after assuming the existence of oscillations, evidence for which is furnished by the striation of the luminous column, thus rendering it analogous to the interference phenomena of a periodically varying source, a distance of 1·5cm. between the striae, which is easily obtained, would correspond to a wave-length of 3 cm. From Hertz's later investigations we know that this represents an electric disturbance, with a frequency of 10,000 million per second. Fluctuations with such high frequencies were no longer observable by the method used, since they do not obey the ordinary laws of electric currents, as was shown by Hertz's later work. I cannot here enter into details concerning the experiments. It would appear that his proof had not satisfied him on this point, for at the end of the Paper referred to he suggests the intermediate assumption, according to which the flow of electricity through a gas is, on the whole, continuous; but that in the tube itself electrical motions of an oscillatory character may be superposed on the constant current, a view which is rendered even more tenable by more recent investigation.

He likewise considered the very important question of the course of the stream lines in a gas traversed by electric discharges. A necessary introduction to this was the proof that cathode rays do not deflect a magnet, although they are deflected by it. It appeared, further, that the cathode rays do not indicate the path of the discharge, but are set up in the course of the discharge, and then obey definite laws of propagation. Experiments upon the absorption of cathode rays were indicated, which have since led to a series of beautiful experiments by Philipp Lenard.

In the last part of this Paper he shows, among other things, that the cathode rays do not exert any electrostatic action, and so they certainly cannot be regarded as electrified particles shot out from the cathode, although many physicists often adhere to, and express, this view.

I should like to refer to the experiments here described concerning the peculiar property of cathode rays, that of bringing about the equalisation of electric potential in a direction transverse to them, and so promoting "transverse discharges," experiments which have been extended by other observers. This behaviour of cathode rays reminds us of a quite analogous property of light-waves, discovered by Hertz; namely, that the ultra-violet waves possess the same equalising power in a high degree.

The general results of the work can be better understood when it is stated that they support a view expressed in similar form by other observers, for example, E. Wiedemann and Goldstein, namely, that the cathode rays consist of a certain form of ether-motion more nearly allied to light than to any other natural agent, and that they are set up by electrical actions; but afterwards constitute an independent phenomenon, just like the light sent out from an electric lamp.

EVOLUTION IN MACHINERY.

It is a great pity that certain branches of science should be encumbered by an uncouth phraseology; it repels the ordinary reader and leads him to suppose that the ideas are difficult to grasp, that the subject is dry, and that the reasoning is complicated. There are many sciences in which dabbling is useless, and of which an elementary knowledge is almost always a superficial knowledge, and therefore inaccurate. So long as evolution was confined to biology, the general public was content to discuss the examples without understanding the general principles; but now that other branches of thought are becoming affected by it, and its application to the conditions of social progress are recognised as of profound importance, an exchange of a few six- and seven-syllable words for more homely ones would be very welcome. That process of change in detail and modification of type; by which machinery constantly adapts itself to the ever-changing character of the work it has to do, follows in many respects the same laws of development as those which express the orderly evolution in the organic world. One of the highest authorities in the sciences of biological and social evolution has defined this process as one of progress "from a state of undifferentiated homogeneity to a state of highly differentiated heterogeneity." The prime "determinants" of the change are, the nature of the environment and the specific properties of the evolving item. In machinery, the nature of the environment has a two-fold influence on the development of the machine type: firstly, in that it determines the character, amount and regularity of the supply of that essential—the energy; secondly, in that it embodies the character of the work which it is the object of the machine's existence to perform. The evolution of electric supply machinery requires to be considered from two distinct points of view, before we can realise that it is one which has its parallels in the evolution of living organisms. It must first of all be considered in relation to machinery in general, and secondly in relation to itself internally.

In the early stages of electric supply, when the requirements of an efficient supply were little understood and less met, it was thought that any type of engine would serve the purpose of motive power, and that any arrangement of plant which

Digitized by Google

could be most conveniently and most cheaply purchased would answer the purposes of generation and distribution. Types of plant by no means adapted to the work were violently forced to perform an unnatural function. Hence, partly at least, the high death-rate among electric supply stations just about that time. But the hardier organisms lived on through the struggle—indeed, have even succeeded in rearing a small progeny—though their ultimate extinction is but a matter of time. The conditions of the new field of activity, however, were on the one hand too important and on the other hand too violently in conflict with the conditions which had moulded the species of machines up to that time, for either the survival of the hybrid species or its complete extinction to occur. Gradually there was evolved a distinct and pure species of plant, and one which was practically adapted to the new requirements. Rudimentary organs there may be here and there, such as eye-bolts, once frequently used for removal of dynamos for repairs. Possibly, even now, there may be traces of imperfect development; but, in the main, the creation of the new field of electric light and power supply has added one more distinct type to machinery, and has advanced by one step more its evolution from undifferentiated simplicity to highly differentiated complexity.

Viewed internally, in relation to itself, the new type or species of plant, which we have called electric supply machinery, exhibits some interesting parallels with the development of species of living plants and animals. Both kinds of species may conveniently be sub-divided into varieties, and again into individuals. In view of the perpetual struggle for existence which is going on among machine varieties, electrical engineers not uncommonly express the opinion that the reduction of the entire species to one dead level must ultimately result; some even believe that such a levelling would be beneficial. Probably nothing of the kind will ever happen; certainly, if it does happen, it will create a precedent, and be distinctly opposed to the ordinary laws of development. Certainly, too, any such reduction of the varieties of electric plant to one type would be far from beneficial. No cant phrase has ever been more misrepresented nor more misunderstood than the one—"the survival of the fittest"—which is usually quoted in this connection. In the first place, as Prof. HUXLEY has pointed out, the "fittest" does not by any means imply the *best*, and, in the next place, the "fittest" in one locality, or under one set of conditions, will be far from being the fittest in another locality, or where other conditions obtain. Fitness consists in the degree of perfection with which the individual or species adapts itself to the conditions under which it finds itself. Not until there is perfect uniformity of conditions in all places can there be any approach to a perfectly dead level of type, and extinction of variety. There are engineering climates, as well as hygienic and social ones. An engine which would thrive exceeding well amidst the belts, pulleys, and shafting of an "old-time" American central station, would find the restricted space and quiet of Knightsbridge or Eccleston-place oppressive and not to be endured.

In quite another respect, if we examine the tendencies of living organisms, we shall be able to illustrate the incorrectness of popular views in regard to machinery. The opinion is not uncommonly advanced, even by engineers, that the tendency in machine design is towards simplicity; and the advocate of this view, having no actual example to support his assertion, generally falls back on the platitude that to expect such a tendency is "only natural." Nature, however, acts quite in the reverse manner. Nor, in face of the history of engineering can it be said that machinery is any exception to the natural rule. The boy who tied a length of string to the valves of his steam-engine, in order that, thereby, they might be made self-acting, took a forward not a backward step in the evolution of machinery; but he made his machine more complicated, by just that one extra detail. Again, a merely superficial comparison of the machinery of a modern steamship with that of the earlier vessels is enough to show how vigorous has been the evolution of detail in structures of this class. It is the function, not the structure, which has a tendency towards simplification. In early types of machines, where the number of parts was small, each part had a multitude of offices to perform, and each set of parts required the close and constant attention of the attendant. Nowadays, we give to each detail fewer duties; we multiply the number of parts accordingly; and we throw in a large number of additional details, to act as links between the others, for the purpose of rendering the entire machine more automatic in its action. Successful machine design can never be consistent with imposing a large number of duties on a single detail which can better be performed by a number of details; and the only scope for simplification lies in the removal of obsolete parts which have no special function to perform, and in the elimination of unnecessary functions. As the physical conditions of human existence become more complex and more refined, it seems probable that there will be a corresponding increase in complexity and refinement in the machinery with which the great forces of nature are directed for "the use and convenience of man."

REVIEWS.

Continuous-Current Dynamos and Motors. By FRANK P. COX. (New York, 1893: The W. J. Johnston Company.)

It should be added to the title of this little book—"Their theory, design, and testing; with sections on indicator diagrams, properties of saturated steam, belting calculations, &c., &c.," for such things indeed are found on the title page. The custom of including disconnected subjects under one general treatise is a relic of an old fashion, when every country gentleman who had "thoughts" would make a book of them, and when such entitles as "Thoughts on Astronomy, with Some Suggestions on How to Behave at Table," were not uncommon. The reader need not stay to inquire into the logic of the combination. It is enough for him that a knowledge of both dynamos and saturated steam is useful to him, and he will do well not to inquire too closely as to why they are both treated between the same covers. The critic, if he too wishes to know the object of offering an elementary student such various fare, may comfort himself with the reflection that this is hardly the sort of book which a serious student would be likely to take to—it is more suited to the intelligent dabbler who, although desirous of learning with accuracy a few elementary facts, by no means intends to follow up his studies along the more advanced and conventional lines. Besides, the critic has recently been warned that any driveller can blame, but it takes a real artist to praise. Still, though this is by the way, there are some books which no kind of real artist could succeed in praising. Many of these, most of these, perhaps, are on electricity. They are, doubtless, written with the intention of developing real art—in the critic. Not that the idea of blaming an author has any direct suggestion from the writings of Mr. Cox in the book before us. Mr. Cox had a difficult task before him, almost an impossible task in fact—namely, to give an exact and intelligible account of the dynamo without the use of more than the simplest mathematical language. His imperfect success is only rendered imperfect by the hopelessness of the task before him. Other writers have set themselves a similar task, but they have all ended in one or the other of two results. They have either been compelled to admit a higher grade of mathematics than

Digitized by Google

was the original intention, or they have cut a sorry figure with inadequate carving implements. It is impossible that anyone can properly understand the details of the subject, as discussed by Mr. Cox, if they have no higher mathematical knowledge than the simple algebra to which he confines himself. This fact is quite independent of the achievement of any particular author, and the recognition of it should ever deter future authors from attempting so much with such little means.

Mr. Cox commences with an elementary exposition of fundamental principles, units, &c.; and we notice that he is particularly lucid in his exposition of why the ohm is a velocity, though he offers no explanation of why the ohm is *not* a velocity. We hope, however, that the reader is not expected to carry the earth-quadrant-per-second idea through the chapters on dynamo design and testing. The sine curves given by all of Mr. Cox's dynamos consist of two straight slanting lines capped with a bit of a circle, notwithstanding which approximation many of the curves are provided with figured scales. The majority of the other curves, however, of which there is a great number throughout book, appear to have been carefully drawn.

In the chapter on the "Design of Armatures" there is a very funny attempt to arrive at the correct proportions of an armature which has purposely been badly designed to start with. The poor armature generates more heat in its iron alone than it can possibly get rid of from its limited cooling surface without overheating, besides which it has a huge copper loss; and the problem the writer proposes is to put things right without upsetting the balance of a lot of other things. The supposition that "if by some miracle the iron loss could be reduced to zero" is reluctantly abandoned; so is the idea of increasing or decreasing the iron section; another tack is followed, and the armature comes out "out of proportion." Sadly, it almost seems, the author drives at still another idea, "has a shot" at it from two or three standpoints, and at last triumphantly exclaims: "We have now designed a Siemens armature which will develop the required potential at the given speed, and will not overheat when operating continuously with the full number of lamps." Then our pulse goes down to the normal, and we breathe once more. But, at the last minute, it is decided to have a Gramme armature, and it happens all over again, this glorification of "trial and error" which they call the design of armatures.

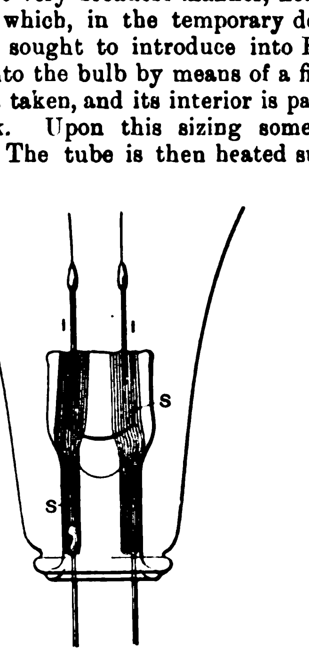
But it does not do to take this type of book too seriously. No one intending to design a dynamo, or to test a dynamo, in anything but an amateur fashion, would think of looking to it for instruction. To the amateur it may prove very pleasant and entertaining literature.

THE POLLARD GLOW LAMP.

The only rational theory of the origin and meaning of "difficulties" is the one which tells us that they are strewn in the path of inventors, manufacturers, and the world generally in order that they may act as anti-soporifics, and be overcome by the very energies they arouse. At any rate, whether this be so or not, would-be American glow lamp makers have evidently regarded the Edison patent, with its apparently indefeasible claim for "the combination of a carbon filament within a receiver made entirely of glass, through which leading wires pass, and from which receiver the air is exhausted," as merely an obstacle to be circumvented. Hence the United States market has been flooded with Maggie Murphy, Westinghouse very-removable-stopper, Beacon, and inert-gas lamps, not one of which, we venture to say, would have lightened our darkness but for the necessity of either evading the Edison patent or "going out of the business altogether."

The latest rival and the latest victim of the Edison monopoly in the States is the lamp invented by Martha W. Pollard, of 113, Otis-street, East Cambridge, Massachusetts, the characteristic feature of which is likely to prove of some value apart from the fact that it would appear to the lay mind to make the lamp a non-infringer, although the United States Courts, taking cognisance of what in this country would be deemed the extraneous consideration that Edison having created an industry is entitled to have his fundamental patent construed in the very broadest manner, hold otherwise.

In the Pollard lamp which, in the temporary default of an American market, it is sought to introduce into England, the current is conducted into the bulb by means of a film of silver. A piece of glass tube is taken, and its interior is painted with a sizing of printers' ink. Upon this sizing some fine silver powder is sprinkled. The tube is then heated sufficiently to



cause the silver to adhere firmly to the glass, and whilst hot the walls of the glass tube are pinched into contact, and the plug thus formed is sealed into the lamp bulb in the ordinary way.

As will be seen by our sketch, the iron wires I I, which conduct the current from the silver films S S to the filament, do not pass right through the glass plug, but are only embedded a little way in it, there being a long length of solid glass beyond. External connection is made with the exposed ends of the silver films by ordinary soldered joints. In all other respects the Pollard lamp is as other glow lamps.

SILK AS A DIELECTRIC FOR CONDENSERS.

In the latest numbers of *L'Elettricista*, Sgr. Luigi Lombardi gives an account of his attempts to construct condensers with silk as a dielectric, instead of mica, paraffin, or other material usually employed. The attempts have, he says, been completely successful, where certain precautions were observed. The chief source of error was found to be the state of humidity of the silk. The desiccation of the sheets of pure white silk and tinfoil was carried out on sheets of brass heated to 200°C., on which the sheets were first placed singly. The dried sheets were kept on a plate at a slightly lower temperature, and were heated to the higher temperature immediately before being mounted in their places. One condenser constructed in this manner contained a hundred rectangular sheets of tinfoil 28cm. by 18cm., separated by double sheets of silk; single sheets having been found subject to short-circuiting. The total thickness was 1·2cm., and the capacity 0·351 microfarads at 21°. The insulation resistance was 10,000 megohms. The greatest variation of capacity was 1·7 per cent., and the sum of the residual discharges after one minute's charge was a little over 3 per cent.

The measurements were repeated after seven months, and gave figures higher by a fraction of 1 per cent. This may be due to an elastic yielding of the sheets under the compressing screws, or to the absorption of a slight amount of moisture, whether contained in the case after sealing up, or admitted subsequently. But there is no reason why this should not be avoided in systematic constructions. As regards the temperature coefficient of the specific inductive capacity, this was found to be of the order of one-thousandth per degree centigrade, positive for rising temperatures.

Silk condensers may be safely used for all differences of potential commonly in use. Measurements with the same ballistic galvanometer, and with potentials increasing by 20 volts up to 200, showed no variation of capacity exceeding 0·4 per cent., and with a large battery of accumulators the first spark passed across the silk at 500 volts. Finally, the material for the dielectric can be obtained at a low cost and of uniform quality in sheets of any size, and could be specially manufactured for purposes of the highest accuracy.

MEASUREMENTS OF THE ABSOLUTE SPECIFIC RESISTANCE OF PURE ELECTROLYTIC COPPER.*

BY J. W. SWAN AND J. RHODIN.

This Paper is a record of measurements of the absolute specific resistance and temperature coefficient of pure electrolytic copper. The authors had the opportunity of comparing a large number of different specimens of electrolytic copper, the origin of which was fully known to them; more material for this kind of research was at hand than has usually been the case. Several specimens of the copper were at first roughly compared, and the best ones chosen for further investigation. The best specimen was then electrolytically refined. It was deposited in the form of a plate, from which narrow strips, square in cross section, were cut, these were filed round, and drawn through sapphire dies to the requisite diameter, the resulting wire being subjected to measurements. The first sample, "A," was measured both when hard and also after annealing at a red heat in an atmosphere of carbon dioxide gas; the second sample, "B," was only examined after annealing.

Aware that the differences in the results obtained by different authorities on this subject are only to a very small extent due to error in the electrical measurements, but are chiefly caused by difficulties in the exact estimation of the sectional area of the wires subjected to measurement, the authors took extreme care in finding the dimensions of the wires and the temperatures at which they were measured. The lengths of the wires taken for examination were measured by comparison with a standard metre rule, and the diameters accurately determined by the specific gravity method, care being taken not to alter the hardness by handling. An apparatus similar to a calorimeter was employed for maintaining the various temperatures required.

The determination of the conduction resistance was made by the fall of potential method, applied so as to eliminate error from variation of the resistance of the leads. From the resistances of the wires at different temperatures, the temperature coefficients were found, and the absolute specific resistance at 0°C calculated.

The values of the two specimens in C.G.S. units were as follows, the density being 8·9587 at 15°C.

——	Absolute specific resistance. C.G.S. units.	Temp. coefficient. Δt.
Sample A. Hard, as drawn	1603	0·00408
" A. Soft, as annealed	1566	0·00418
" B. Soft, as annealed	1559	0·00415

The mean of the values for the two specimens of soft copper is probably the correct value. As a general conclusion it is stated that probably the following express the true values for the two varieties:—

	C.G.S. units.	Δt.
Hard variety	1603	0·00408
Soft, or annealed	1563	0·00416

PROPOSED ELECTRIC TRANSMISSION OF POWER FROM THE TROLLHÄTTAN WATERFALL, SWEDEN.

Last autumn a Royal Commission was appointed for the purpose of investigating the important question of electrically utilising the Trollhättan Waterfall, and their report is now completed. In the first place, says our Scandinavian correspondent, they claim for the Crown full proprietary rights of several islands in the river, where the Crown, consequently, is at full liberty to erect generating stations. In addition to these islands, the Crown is the owner of some land on the border of the river, which would be admirably adapted for the building of industrial establishments, for which electricity could be conveniently provided. The Commission has been at great trouble to ascertain the water-power available, and the outcome is an apparently reliable calculation, according to which the Swedish Crown has here at its disposal no less than 49,000 H.P. The Commission proposes that the Government shall utilise 20,000 H.P., and erect two separate stations of 10,000 H.P. each, the second of which, however, is only to be taken in hand when the whole power of the first station is employed.

At the Gullön island there is to be a 10,000 H.P. station, for which 74 cubic metres of water per second (16,280 gallons) is to be taken from the Gullö-Toppö course of the river. Having passed the Upper Gullö cataract, the water would be conveyed to a reservoir, blasted out of the rock, from which it would again proceed to the turbines through a tunnel, also blasted out of the rock, 770ft. long, which will have its exit at the lower border of Stora Toppö Island. The fall from the reservoir to the bottom of the tunnel will be about 51ft., and the effective fall from the turbines 48ft.

With an aggregate water consumption of 74 cubic metres per second, evenly divided between 10 turbines, and with a percentage efficiency of 72·5 per cent., there will be an available effective power of over 10,000 H.P. Each turbine is to operate entirely independently. Alternate-current generators and transformers will produce a current at a pressure of 15,000 volts.

When this power has been fully utilised, it is proposed to build another station of similar capacity at the Spikön Island, for which the water would be taken from the course of the river on the west side of the Gullön Island, the Nolström fall. From here a tunnel of about 1,030ft. would be carried under the river to Gullö, and fall into that tunnel, which from there goes to Stora Toppö. This latter tunnel would, therefore, from the outset, be made so as to have sufficient capacity for taking the water for both installations. The Spikö installation will thus have greater effective fall than the Gullö installation—viz., 53ft.—so that nine turbines, with a consumption of 66 cubic metres of water per second (14,520 gallons) will be sufficient to produce 10,000 H.P.

The next question is how this power of respectively 10,000 or 20,000 H.P. can be used in the best manner? The whole or part of the power might be led to some Crown property—Stallbacka, for instance—where a receiving station might be erected, and from where the power could be distributed to the various industrial establishments which it is expected would spring up; or the power, the whole of it or otherwise, might be conveyed to Gothenburg, where, according to calculations, the electric power could easily compete against the steam power at present used, which amounts to some 6,500 H.P. It might, therefore, be advisable to bring 5,000 H.P. to Gothenburg, where it would be received by two receiving stations. Customers who can do with some hundreds of horse-power, and who can provide their own lines, may rely upon very cheap power, although it is not considered necessary to fix a lower charge than 80kr., or £4. 9s, per horse-power per annum. The cost has been estimated in various ways.

A. For providing and conveying to Stallbacka electric current to the extent of, say, 3,000 H.P., with receiving station there.

B. For producing and conveying to Gothenburg electric current to the extent of, say, 5,000 H.P., with two receiving stations there.

C. For producing and conveying to Gothenburg 10,000 H.P., with three receiving stations there.

In all three cases the installation at Trollhättan is built ready for the production of 10,000 H.P., but the greater the power the smaller, naturally, is the cost per horse-power, and the greater the profit, exclusive of 4 per cent. interest on the capital. Scheme A is estimated to result in a net profit of 4·82 per cent., scheme B 7·8 per cent., and scheme C 10·55 per cent. The estimated costs are—for A £47,000, for B £86,000, and for C £147,000. The annual outgoings are estimated at respectively £4,600, £8,800, and £15,500.

PARLIAMENTARY INTELLIGENCE.

LONDON, WALTHAMSTOW AND EPPING FOREST RAILWAY.

This Bill, which had given rise to a controversy between the promoters and the London County Council on the question of workmen's trains, and which had been recommitted to the same Committee, was dealt with on Monday. It will be remembered that originally the Committee, at the instigation of the London County Council, decided that the charge should be 1d. for nine miles up to 8 a.m.; whereupon the promoters, declaring that they would not be able to raise their capital upon those terms, declined to proceed with the Bill. Since then further negotiations have taken place, with the result that the following clause was agreed upon:—

(1) The Company shall at all times after the opening of the railway, or any part thereof, for conveyance of passengers run or provide a sufficient number of trains for the conveyance of workmen, which shall stop either at all stations or at such stations as may be required, and shall be timed to arrive in London up to but not later than eight o'clock on every morning of the week except Sundays, Christmas Day, Good Friday, and Bank Holidays.

(2) The fares by such trains shall not exceed at any time—

For a distance not more than nine miles, and the return journey, fourpence.

(3) From and after the expiration of five years from the opening of the Railway, or any part thereof, the fares by such trains shall not exceed

* Abstract of a Paper read before the Royal Society.

Digitized by Google

at any time for a distance not more than nine miles and the return journey—

By trains required to be run, or provided under this section timed to arrive in London up to, but not later, than 7:15 in the morning, twopence;

By trains required to be run as provided under this section timed to arrive in London after 7:15, and up to, but not later, than eight in the morning, fourpence.

(4) "London" shall for the purposes of this section be deemed to include the stations at or near South-place, Finsbury, and Kingsland-road, and any station that may be erected between those places.

(5) A return ticket issued in pursuance of this section shall entitle the holder to return in a third-class carriage by any train during the day, and to leave the train at the station from which the holder started, or at any intermediate station at which the train shall stop.

(6) The Company shall publish and keep published in some conspicuous and convenient part of every station on the railway notice boards or placards setting forth the conditions on which workmen's tickets are issued, the fares charged in respect thereof, and the trains by which such tickets are available, and shall also publish the like information in their book of time-tables.

(7) The liability of the Company under any claim to compensation for injury or otherwise in respect of any passenger travelling by any trains run or provided under this section, or any passenger returning at a fare fixed under and for the purposes of this section shall be limited to a sum not exceeding one hundred pounds.

(8) On complaint being made to the Board of Trade with respect to the sufficiency convenience, number or times of workmen's trains arriving in London in the morning, or the sufficiency of the accommodation provided thereby, the Board of Trade may after inquiry order the Company to provide such further trains or accommodation as, having regard to the circumstances, may appear to the Board to be sufficient for the purposes of this section.

Sir John Kennaway, on behalf of the Committee, endorsed the Bill with this clause in it, and it was then formally ordered to be reported for third reading.

THE LONDON COUNTY COUNCIL AND THE EPPING FOREST ELECTRIC RAILWAY.

At the meeting of the London County Council on Tuesday the Parliamentary Committee reported that they had been in further communication with the promoters of the London, Walthamstow, and Epping Forest Railway with reference to the insertion of clauses providing for cheap workmen's trains. The committee had consented on behalf of the Council to terms with the promoters by which the opposition to the Bill would be withdrawn.

Alderman Fleming Williams said that the proposals contained in the report had been very carefully considered by the Public Health and Housing Committee, and by an almost unanimous vote the Committee had instructed him to move to refer the report back for further consideration. He did not in the slightest degree desire to cast any blame on the Parliamentary Committee for the special character of the recommendations which were contained in the report. He had no doubt the Committee had done the best that was possible under the circumstances, but the best they had done fell far short of what they in the Public Health and Housing Committee regarded as desirable.

Mr. Westacott: Is it not a fact that the Committee of the House of Commons have passed the Bill with the conditions contained in the report?

Mr. Charles Harrison (the Vice-Chairman) said the Bill passed its third reading that afternoon.

Alderman Fleming Williams said he was sorry to hear it, for it placed the Council in an exceedingly undesirable position. All he could do now was to enter his protest against what seemed to be a very unfortunate course, and one which fell little short of a disaster. They had missed a splendid opportunity of insisting upon an adequate and suitable service of workmen's trains. He knew that Mr. Harrison thought he had made moderately fair terms with the promoters, but if he had had the backing of the whole of the Council he would have made a much better bargain. The new line under present conditions would not relieve in the least the over-crowded cheap service on the Great Eastern, because the fares would be much more.

Mr. Torrance was exceedingly sorry that the Committee had not been able to do more for the thousands of working men and women who so much required their help. He had lived in the City for thirty years, and he knew that there were thousands to whom cheap trains running up to 8 a.m. would have been an inestimable boon. They came up by the early workmen's trains, and had to wait about in the streets in all weathers for an hour or more until it was time to go to work, because they could not afford to pay the ordinary rates charged for later trains. If the people of London were not to look to the Council for help in this matter, to whom were they to look? If our legislators had witnessed the waiting about that he had himself, the law would have been altered before this.

Mr. Charles Harrison said the Parliamentary Committee had made the best terms possible. He supported the Council's demands before the Select Committee, and the Committee accepted them, with the result that the promoters withdrew the Bill on the ground that it would be impossible to raise the capital required.

Mr. Lloyd moved an amendment: "That the Council do oppose the Bill in its further stages through the House of Lords, in order to secure the insertion of provisions making the 2d. return tickets available up to 8 a.m., and the 4d. tickets available up to 8:30 a.m."

Alderman Ben Tillett supported the amendment, because, having travelled much by the workmen's trains on the Great Eastern Railway, he knew what a great boon it would be to vast masses of working people. Morning after morning he had seen men and women crowded into the Great Eastern trains like herds of cattle. A considerable proportion of those who travelled by the trains had to wait about for an hour or so, and as many of them were women earning only 7s. or 8s. a week, the Council would realise what an extra shilling a week to come by a later train meant to them.

The Council divided, with the result that the amendment was lost by 52 to 28, and the action of the Committee was approved.

Alderman Beachcroft suggested that the Vice-Chairman should confer with the promoters of the Bill with a view to have a clause inserted so that it should be made clear that the Company would not, by reason of the terms now arrived at, be relieved from any obligation that might otherwise be placed upon it by virtue of the Cheap Trains Act, 1883, or any other statute hereafter dealing with the subject of cheap trains.

CORRESPONDENCE.

HERTZIAN WAVES IN LABORATORIES AND ELECTRO PLATING WORKS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In the issue of your valuable paper of June 8, 1894, under the heading "Hertzian Waves at the Royal Institution," you take occasion to remark: "It is wholly probable, as Dr. Lodge suggests, that Hertzian waves may often have manifested themselves in physical laboratories to the annoyance of the workers," &c.

I may mention in this connection that in 1877, if I remember the year correctly, while working a Ruhmkorff induction coil, one terminal of which was grounded, and the other terminal of which was attached to an insulated metallic body, Prof. Houston and I noticed that when the sparks were passing between the terminals of the coil, it was possible not only to obtain minute sparks from all metallic bodies in the immediate neighbourhood—that is, in the same room—but that delicate sparks could be taken by holding in the hand a small piece of metal near metallic objects in many other rooms and on different floors in the building, although the pieces were not connected to ground. These could only have been Hertzian effects, but there was no recognition of their true character at the time, though the effects were seen to be connected with the very quick charging and discharging of the insulated body. An account of these experiments was, I think, published in the *Journal* of the Franklin Institute at the time.

I desire also to mention, as coming under my notice within the past year, a curious and rather amusing illustration of the principle upon which the beautiful instrument for detecting the presence of electric oscillations devised by Dr. Lodge, and called by him the "coherer" is based. It was reported to me when in Philadelphia that a certain electro-plater had found that he could not pursue his silver-plating operations during thunder-storms, and that if he left his plating over night and a thunder-storm came up the work was invariably ruined. I was disposed to be thoroughly sceptical, and expressed my disbelief in any such effect. Being urged, however, I went to the silver-plater's shop, which was a small one, and questioned the silver-plater himself concerning the circumstance which had been reported. While it was evident that he was not a man who had informed himself electrically, I could not doubt that, after conversation with him, he had indeed been stating what was perfectly true; namely, that when his operations of plating

Digitized by Google

were going on and a thunderstorm arose, his batteries, which were Smee cells, acted as though they were short-circuited, and the deposit of metal was made at too rapid a rate. The secret came out on an inspection of his connections. The connections of his batteries to his baths were made through a number of bad contacts, which could not fail to be of high resistance under ordinary conditions. I could readily see that virtually he was working through a considerable resistance, and that he had an excess of battery power for the work. Under these circumstances a flash of lightning would cause coherence of his badly-contacting surfaces, and would improve the conductivity so as to cause an excessive flow of current, give a too rapid deposit, and, as he put it, "make the batteries boil." The incident suggests the use of Dr. Lodge's ingenious instrument in the study of the waves which are propagated during thunderstorms, of which waves we have practically little or no information.—Yours, &c., ELIHU THOMSON.

"CATALOGUING SCIENCE."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It has occurred to me that the expense of preparing abstracts for the proposed international catalogue of scientific Papers referred to in the leading article of last week's *Electrician* might be almost entirely avoided in the case of *future* Papers, if it became customary for the author of a Paper to conclude it with an abstract drawn up according to such rules as to length and form as might be prescribed by the future international bureau.

In order to introduce the custom the leading scientific societies and periodicals might make it a rule that every Paper should be accompanied by such an abstract. It would then, probably, soon become quite general.

Abstracts prepared in this way would be better and more reliable, which would be a still further advantage.—Yours, &c.,

WILLIAM LUCAS.

CURRENT-RUSHES INTO TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It was with no small surprise that I read Dr. Fleming's letter in your last week's issue. The only inferences which I can draw from this letter are: (1) That he has not *read* my Paper; (2) That he credits me with a surprising amount of ignorance on the very matter of which I treat. He is good enough to refer me to his Paper read before the Institution of Electrical Engineers in 1892. Will he kindly take the trouble himself to refer to § 1 of my Paper (p. 229), the opening sentence of which runs thus:—"Since the publication of Dr. Fleming's Paper on 'Experimental Researches on Alternate Current Transformers,' read before the Institution of Electrical Engineers in November, 1892, it has become generally known that under certain conditions there is an abnormal rush of current into the primary coil of a transformer at the instant of connecting it to the supply mains." Clearly, Dr. Fleming's recommendation to me to study his Paper and the discussion thereon is somewhat superfluous. Dr. Fleming will also see that I have been careful to give him all due honour for having been the first to investigate the interesting phenomenon of impulsive current rushes.

If Dr. Fleming had taken the trouble to read the introductory portion of my Paper carefully, he could not have failed to notice that the theoretical conclusions which I arrive at in §§ 4—6 apply to a circuit *which does not contain iron*; these conclusions were thus never meant to account *fully* for the current-rushes in transformers. The whole of his criticism on this point, therefore, falls to the ground. The sentence which seems to have caused particular offence, viz., that I was not "aware of any experimental evidence for these current-rushes" (in circuits of constant permeability, as is amply evident from the context) I must still uphold—unless, indeed, Dr. Fleming is prepared to refer me to experiments on this point, or to curves *obtained experimentally*, such as those which appeared in last week's *Electrician*, p. 262. Not a word regarding current-rushes in coreless coils is mentioned in the Paper alluded to above.

Dr. Fleming claims to have investigated "experimentally in the fullest possible manner" the phenomena of current-rushes. Whatever this assertion may mean, if it refers merely to the experiments described by Dr. Fleming and Mr. Mordey in the Paper already referred to, I must absolutely deny that the experimental investigation is either full or satisfactory. Among other things, Dr. Fleming refers in his letter to an experiment made by him to determine whether the rush is unidirectional or alternating. This experiment is described on page 682 of the *Journal* of the Institution of Electrical Engineers, Vol. XXI., and the conclusion arrived at there is that "probably the rush of current is an alternating rush." This view, however, is corrected later on, page 97 of the *Journal*, Vol. XXII., where it is stated that "the whole effect is over in less time than one period." No statement could be more utterly misleading and erroneous. For experimental proof of this I have merely to ask Dr. Fleming to refer to Fig. 6 of my Paper, appearing in this week's issue. The hysteresis loop given by Dr. Fleming on page 98 of the *Journal* is also far from being correct. I hope to publish the correct form in the next instalment of my Paper.

It is not, however, my object to pick holes in Dr. Fleming's statements, and what I have said is merely on account of the half-dictatorial, half-patronising tone about his letter which provokes criticism. I hope my statements will have the effect of shaking Dr. Fleming's confidence in some, at any rate, of his conclusions, and possibly even of leading him to think that the publication of my series of articles is not *altogether* superfluous, and that it is indeed premature to criticise a Paper, only a small portion of which has as yet appeared.—Yours, &c.,

University College, Nottingham. ALFRED HAY.

ENGINE REPAIRS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We have read with much interest the continuation of the article on "Electric Motive Power," by Mr. Albion T. Snell, in your number of the 16th inst.; but upon one paragraph we should like to say a few words.

We are aware that in stating that the repairs to a closed type of engine take a long time to execute, because the casing must first be removed and the rods, &c., cooled, Mr. Snell is only giving expression to an opinion which is commonly held among engineers; the idea is, however, mistaken.

In the Willans engine the only parts which have to be removed are the doors in the casing, each of which can be removed in a few seconds by slackening a single nut. (As now made they are considerably larger than the doors shown in your illustration.) The crank-shaft, main bearings, connecting rods, and brasses are then accessible for inspection or repair, the doors being sufficiently large to allow repairs to be effected. The casing itself, which really forms the standard carrying the cylinders and cross-head guides, does not require to be removed. Even in the event of the cross-head guides requiring examination, the removal of the casing is not necessary. By lifting off the cylinders every part of the engine can be completely exposed. That this is not a lengthy operation is evident from the photograph of our works engine, shown at the Institution of Civil Engineers on the occasion of the reading of the Paper by the late Mr. Willans on "Economy Trials of a Condensing Steam Engine," which we enclose, together with a copy of the note attached.

[This engine was driving Messrs. Willans and Robinson's works as usual at one o'clock this afternoon (April 18, 1893). The parts shown (including everything but the base) were removed during the dinner-hour, and replaced by similar parts taken from store, and the works were restarted as usual at two o'clock. This engine was fixed in July, 1889, and has had unusually severe running, probably equal to nearly five years of ordinary running. No part has been replaced except one piston-ring, and there are very small signs of wear in any part.—April 18, 1893.]

We might even ask if there has ever been another case in which a 60-H.P. factory engine has been completely dismantled, with the exception of the bed-plate, and replaced by a new one ready to begin work, *within one hour* after stopping the works. Remember that the crank chamber upper part (casing), drawn out of store, fitted on the old lower part, *made four years previously*; that the new crank shaft, with its brasses (also drawn

Digitized by Google

from store), went into the old bearings; and that the new fly-wheel, also a standard one, had to be coupled up to the old first-motion shaft.

The parts of these engines are light, and can be removed by simple lifting; all packing is metallic, consisting of springs and rings, and the steam joints require no making, being plain metal to metal. Re-erection is therefore easy.

As regards the cooling of the rods, the case of the 60 I.H.P. engine is in point, but in the later engines the temperature of the lubricant in the crank chamber rarely reaches 150°F. in condensing engines, or in non-condensing engines, when, as is desirable, a portion of the feed water is taken through the lubricant in cooling pipes. All parts can be got at without touching the lubricant—its level being sufficiently low to allow of this being done—and, consequently, by the use of a little waste there is no difficulty in removing any part in the crank chamber almost immediately after stopping the engine. We should like to see a competition in quick repairs.—Yours, &c.,

(For Willans and Robinson, Limited) A. LAZENBY.

Picton House, Thames Ditton, Surrey, July 10, 1894.

LEGAL INTELLIGENCE.

Re Woodhouse and Rawson United (Limited).

FRIDAY, JULY 6TH.

Mr. SAMUEL POPE, Q.C., was the first witness called. Examined by the Official Receiver, he said he was not one of the original Directors of the Company, but was appointed on August 5, 1889, at the same time as Sir Rawson Rawson and Sir Leopold M'Clintock. He certainly should not have objected to his name appearing on a prospectus as a Director after he had consented to join the Board, although he had not actually been elected. The prospectus dated July 15th, purporting to be a copy of the original prospectus, and containing his name as one of the Directors, was issued without his knowledge; but he did not know that he should have objected to it.

Mr. JENKINS said that prospectus was never sent out.

The OFFICIAL RECEIVER: 500 copies were printed.

WITNESS: I have no doubt there were several draft prospectuses got out, and if I had given my consent I should not have objected to my name appearing on it.

The OFFICIAL RECEIVER: This is a copy of the original prospectus sent out, and which offered 200,000 Ordinary shares, 150,000 Preference and 100,000 Debentures, stating that the list will open on Monday, July 22nd, and close on or before Wednesday, the 24th.

WITNESS: It is obvious I could know nothing about that, because I was not appointed a Director until August 6th.

The OFFICIAL RECEIVER: That is the point I want to get at. That is the original prospectus containing the names of Sir Albert Cappell, Sir John Coode, and Col. Howard Vincent. Those three gentlemen resigned. This prospectus, it appears, was printed by order of somebody connected with Woodhouse and Rawson. It is an almost identical copy, except that your name, Sir Leopold M'Clintock's, and Sir Rawson Rawson's are given as the original Directors, so that anybody subscribing under that prospectus might naturally suppose that you personally had looked into all these matters stated in this prospectus.

Mr. JENKINS: I think, if the question is to be asked, it should be shown that somebody got a copy of that prospectus.

WITNESS: I do not quite understand to what the question is pointed. Of course, I did not see the prospectus, or was not a party to issuing it until I was appointed a Director, but I should expect that the prospectus would go through several drafts before being issued, and for all I know you have got hold of one of those drafts.

The OFFICIAL RECEIVER said he was not trying to fix any responsibility upon the witness, but merely to bring out the point that Mr. Pope's name was included in the prospectus as if he had joined the board prior to July 15th.

Mr. JENKINS: Then the document speaks for itself.

WITNESS: The inference I draw from that is this. Before July 15th I must have been asked to become a Director and given consent, and whoever did that presumed that what I had given my consent to I should not wish to withdraw from.

The OFFICIAL RECEIVER: That cannot be quite the case. The explanation given in Court yesterday by Mr. Rawson was that a number of fresh copies were printed in case anybody should apply for a prospectus or a copy of the prospectus.

Mr. F. L. RAWSON: It was not a prospectus issued to individuals outside for the purpose of getting capital.

WITNESS: At the first meeting I attended I inquired whether proper investigation had been made with regard to the businesses about to be taken over, and I was assured by Lord Aberdare, then in the chair, that a most careful investigation had been made, and that it was unnecessary for me to incur the time or expense of a second investigation over and above that, because I might be perfectly assured that the Directors had taken every pains to ascertain the correctness of those statements. I accepted that without going further.

The OFFICIAL RECEIVER: Then you did not personally inquire into the facts as to whether the profits of the Limited Company for 1888 were £21,440?—No. I accepted Lord Aberdare's assurance that that had been previously done, and, further, I had an interview with Sir John Coode, whom I knew as a most cautious man, to ascertain whether there was any dissatisfaction upon this head, and he assured me there was not. He told me that he found the subscriptions from the public were not what he had been led to anticipate, and he did not desire to be associated with a company whose working capital he regarded as inadequate. He expressed not the slightest dissatisfaction with anything else.

Did you understand that the business was to be mainly industrial or financial?—I understood that the backbone would be the industrial business, but that the opportunity would be afforded to form companies to work any electrical inventions which our business might enable us to investigate. I should like to say this emphatically, that I cannot comprehend how anyone who attended any meeting of the new Company could doubt as to what its purpose was. It is clearly defined in the Articles, and it is not only so, but I myself and Lord Aberdare, at the first meeting held, expounded to that meeting that it was impossible for the profits shown to have been accomplished by a purely industrial business. I do not comprehend how anybody could have misunderstood the matter. Even on that prospectus I cannot understand any difficulty in the matter.

Is there any reason why it should not have been stated clearly?—I know of none, for we had the anticipation that the financial part of it would be an immensely profitable part of the business. We believed that the boom in companies, and especially in electrical companies, would be perpetual. If it had been perpetual we should not have been here now.

As regards what was taken over, the agreements entered into, did you also adopt those without personal inquiry?—I felt a little bit sat upon when I, coming new on to the Board, proposed to go over again that which the Directors told me had given them so much trouble. I accepted their assurance that it had been gone carefully into. I felt a little bit snubbed when I suggested a further investigation might be interesting to me.

In 1890 the patents appear in the balance-sheet as £74,000. I want to know whether the Directors or yourself took any steps to ascertain whether that amount really represented the value of the patents at that date.—I did not personally take any steps, but no doubt the Directors made any inquiries they thought necessary, and took the opinion of the men best qualified, having more technical knowledge. On every occasion I was at the Board and the balance-sheet was discussed the greatest care was taken by the Directors in informing themselves from such sources as were available as to the correctness of the assets. I do not know that any special investigation was made into the patents; but the whole of the assets were inquired into.

One large source of value in the patents was the lamp patent?—I always understood, in a general sort of way, that one of the most valuable patents was the lamp patent.

That was being worked by the Company under an agreement with the British Company?—That was not sufficiently direct to please me, but I confess I felt bound by higher authorities than myself in such matters when they said that was the proper way of dealing with it.

The Edison-Swan Company had, I think, in the commencement of 1890 commenced an action to restrain this manufacture?—So I understand.

So, at the end of the financial year 1890 there must have been considerable doubt as to that portion of the value?—Not necessarily so, because a patent might be applicable, notwithstanding that in England it was an infringement upon the patent of Edison and Swan, and I understood that Lord Justice Davey had himself intimated that if the manufacture were conducted even in England upon the basis that the shareholders contended for that that would prevent the patent from being an infringement. I, of course, except for the difficulty that Edison and Swan would not allow it if they could help it, would very much rather that we made the incandescent lamps ourselves. I think, further, that if we had been able to develop a trade in incandescent lamps at that time that would have formed a very valuable portion of the business.

You did not allow anything for diminution of value on that special patent?—As the balance-sheet was first prepared there was no question as to that; but ultimately, upon the report of the auditor, there was a reduction made in the value of the patent. I remember we had a discussion as to what the depreciation should be, and we came to the conclusion that the period of the expiry of the patent should be the basis. There was no special sum reserved to meet the possible effects of this action.

Continuing to reply to questions, WITNESS said he was not aware that nearly all of the industrial businesses showed a loss until some time afterwards. It was represented to him that they were doing as fairly well as under the circumstances of a new industrial business could be expected. He always understood, and told the shareholders at every opportunity, that the industrial business could not be expected to yield the profit to provide the dividend they were receiving. He became a Director of the Okonite Company, but he knew nothing of a cheque of that Company for £30,000 being held over, at the Company's request, for a week, nor that in the meantime the United Company, through Mr. Rawson and certain nominees, applied for shares in the Okonite Company, their application money going to supply the money for that cheque. He had some idea that the United Company did apply for shares in the Okonite Company, but he did not know whether those applications were formally authorised by the Board. He was not even now satisfied that the industrial business was conducted at a loss; he should doubt that it was so. He considered the proposal under which the guarantee fund was returned was so eminently satisfactory and in the interests of the shareholders that he did not vote against it, but, on the contrary, approved of it. If he had known the business was being conducted at a loss he would not have been a party to the representations made to the shareholders that it was not. He thought, if it were the fact, the shareholders should have been made aware

Digitized by Google

of it. But it had not yet been proved that it had been carried on at a loss. In 1892 he became aware by some process that it was desirable that some special measures should be taken to stop what he then became aware was a leak in the industrial business, and at that period they devoted great attention—constant, wearisome attention—to endeavour to accomplish that purpose. With regard to the return of the guarantee fund, even now he thought that transaction was reasonable, and in the interests of Woodhouse and Rawson United. They were at that time being pressed by the liquidators of the Limited Company; he, personally, had an interview with Mr. Hoster, in which he told him that the profits, as disclosed by the balance-sheet of 1890, showed such figures as to entitle them (the Limited Company) to demand either a rapid payment or some setting aside of the funds that were so shown in the balance-sheet to exist, in order to liquidate that £75,000. Mr. Hoster acted most strenuously in the interests of the old concern, threatening litigation, and a very early impression which he (witness) gained was that the antagonism between Mr. Hoster and Mr. F. L. Rawson arose from the circumstance that the former looked to no interest but that of the old concern, whilst Mr. Rawson sought also to serve the new concern. Relations became very strained between them in consequence of the vigour with which Mr. Hoster put forward the claims of the Limited Company. He (witness) was perfectly certain they would be prevented from issuing new capital by Mr. Hoster unless they did something to set aside that guarantee. That stood in the way of the completion of the liquidation, and when he saw they could by arrangement dispose of that difficulty, and carry out a transaction which in itself seemed to be somewhat advantageous for the Company, he thought they were bound to do it if the shareholders would permit them. The expression "realised profits" was one which he did not understand in connection with a balance-sheet. It might be a very prudent thing for a partnership to say they would not divide their profits until they had actually ascertained them, but it seemed to him that in a company that could not be done, and that the only question was whether at the time of the balance-sheet the assets presented were fairly and reasonably and *bonâ fide* valued. The shareholders who existed at that time were entitled to the profits of that year, and the Directors were not entitled, under the statement that the profits were not realised, to refuse to credit the shareholders of that year with the profits which they had earned at a fair valuation. He did not say that if they had proposed to their shareholders to postpone a dividend until all the assets had been realised it might not have been a prudent thing to do, judging by the circumstances which had arisen since, but he could not conceive that a body of shareholders would have assented to it. He was aware that the basis upon which the Okonite Company's business was purchased was an old valuation, and a difficulty arising through the gentleman who was to become Managing Director declining to admit that valuation, Mr. Vaughan Stephens was sent to America in order to obtain a restitution of some of the assets which had been sold, and the result was the return of £20,000 of the purchase money in shares. He should like to say that the Okonite Company was at this moment a prosperous concern in America. The American shareholders intervened, and turned all the English directors out. That Company had weathered very satisfactorily the terrible financial storm which had passed over all industrial businesses. No dividend, however, had yet been paid on the Ordinary shares. When he learnt that the Managing Director of the United Company (Mr. F. L. Rawson) was connected with the Phœnix Trust Company, and that there was also associated with that Company a man whose name was well known in the City, and who, whatever his ability might be, did not seem to him calculated to add to the prestige of their Company, he was earnest in urging the separation of the Company from a company so managed. He had not known that the Epstein Company was floated on the last day of the financial year until he read of it in connection with these proceedings. His impression about that Company was that if Woodhouse and Rawson had been able to do their duty by that Company and supply it with means it would have been, and would now be, a prosperous concern. He would not have been connected with this Company if he had not caught the electric fever, like so many other people. That brought him into contact with some of the most eminent electricians in the world—Lord Kelvin and others—and before accepting the valuation of the Epstein shares he made every inquiry as to what was the value of the electric accumulator, and he satisfied himself that it ought to be a highly valuable enterprise, for it solved many of the most difficult questions which had been perplexing electricians, especially with regard to traction, for a very long time. It was the fact that the Directors of the United were continually borrowing money during 1891, the reason being that they were very anxious not to call up the shares; he had no share himself in such scruples.

By Mr. PILLING: In February, 1888, he became a shareholder in Woodhouse and Rawson (Limited) to the extent of £500, and in December of the same year he bought 571 Ordinary shares on which 35s. had been paid. When he became a Director of the United, being a little doubtful as to the exact nature of the qualification required of a Director with regard to his holding, he applied for and obtained a sufficient number of shares in the new Company to qualify him apart from his transferred interest in the old Company. Ultimately his interest in the old Company was converted into 115 Preference fully-paid shares and 172 Ordinary fully paid. He had never sold a share. No such dream ever entered his imagination as that he would get his money back four times over from the Limited Company. With regard to the advantage to be gained by the repayment of the £75,000 guarantee, in the first place it was not a cash balance; it was simply a retention of purchase money which would become payable in cash about twelve months later. They must have been then prepared to find £75,000 in sovereigns. In the next place they were able by the arrangement made to reduce that amount by £12,000. Then Mr. Hoster insisted, although witness could not see how the liability arose, that the earnings amounting to £42,000, shown on the balance-sheet ought to be passed to the credit of the £75,000. The only mistake he made, as it seemed to him, in the calculation of the advantage was that he did not at the moment realise that they were converting a debt not bearing interest into a debt which did bear interest.

Mr. PILLING: Had you it on your mind that there was a great overvaluation of the properties acquired?

WITNESS: Do you not see that you are asking me whether I was consciously a fraud?

WITNESS further said he assented to the settlement of Mr. Rawson's account, but resented the suggestion that it was "squared off." In reply to Mr. M'Kay, who put numerous questions as to whether he approved of the issue of the prospectuses, WITNESS said: If I am responsible for the prospectus, I am responsible for it. If I am responsible you must establish my liability. Whatever liability attaches to a Director I cannot set myself free from. I have never repudiated it, and if it is necessary that I should, in order to relieve myself of liability, I have never taken that step.

By Mr. H G. RAWSON: With regard to the account with the Managing Director, his recollection was that long before the completion of the matter there was an arrangement whereby the Managing Director would receive his payment in debentures, and it was considered only fair that he should be entitled to pay his debt in the same way. Sir Rawson Rawson impressed him from beginning to end with the value of his independent services to the Company; he had had a very considerable experience of Chairmen in other companies, and he had rarely seen a more industrious and painstaking Chairman. He had from various causes been very much interested in the Epstein accumulator, especially after the inquiry last year regarding the interference of existing forms of electric traction with telephone and telegraph wires, and his opinion of the value of that accumulator had not altered in the least.

In conclusion, WITNESS said there was just one grain of comfort to him, notwithstanding the unfortunate result of his share in the management had been considerable loss to so many, and that was the absolute knowledge that not one of the Directors had put a single halfpenny in his pocket at the expense of the shareholders.

Mr. STUTCHBURY was recalled, and, in reply to the OFFICIAL RECEIVER, said he had prepared a balance-sheet which showed a loss of £15,000 on the industrial business. He took the Phœnix Trust shares at £25,000, and the Epstein shares at the amount paid for them, £4,000, the amount spent on the Epstein Company was treated as a book debt. The extension of the financial accounts in 1891 to the end of July was done at the direction of the Board, but he did not know their reason for adopting that course. The effect of the extension was undoubtedly to include the Epstein profit, and if that had not been included there would have been a slight loss on the year, or the accounts would have just about balanced. Had the accounts of the industrial business been extended to the same period it would have increased the loss by about £4,000. He had stated that the values placed on the shares and debentures held by the Company in other companies, the stock-in-trade, the goodwill and patents, and the debts due to the Company, were all over-estimated. The Managing Director was in daily communication with Baron Grant; he did not think the Directors were aware of the Managing Director's connection with the Phœnix Trust when that connection was first formed. Letters and circulars were sent out with his name attached to them, which he did not see until after they were sent. He remonstrated with the Managing Director upon one occasion, and the latter was more careful afterwards. There was a constant scarcity of funds in 1891, and witness suggested to the Chairman of the Board that it would be a good thing if the Managing Director would discharge his debt to the Company instead of their borrowing money, but no action was taken upon that suggestion. He believed many attempts were made to realise some of the securities held by the Company, but unsuccessfully. The Maskelyne typewriter was brought to the notice of the Company by Mr. Baker, and a proposal was made that Mr. Baker should join the Board of the Maskelyne Company. Eventually an order was given for the manufacture of certain machines at a certain price, to be delivered within a certain time. Owing to a combination of circumstances the machines were not finished in the time; the Company was hard up for money, and the Maskelyne Company threatened an action. The witness thought the best course would be to resist the action, but the Directors thought that would not be wise, and agreed to sell to the Typewriter Company the whole of the plant and tools, the finished and unfinished machines, for £5,000 or £6,000—paid in debentures.

By Mr. JENKINS: He made up the balance-sheet showing a loss on the industrial business from the balance-book and the profit and loss account, including several sums, such as salaries, wages, &c., really belonging to the industrial account, but not credited to that account in the books.

The further hearing of the case was adjourned until Tuesday.

TUESDAY, JULY 10TH.

Mr. STUTCHBURY again went into the box, and his examination by Mr. Jenkins was continued. He became secretary of the Company in the middle of January, 1891. He was asked by the Official Receiver to get out certain figures, as he wished to check some figures of Mr. F. L. Rawson's. The sheet showing the accounts for 1890 was compiled by Mr. Fox, the Official Receiver's clerk, with the apportionments given by witness of expenses to different departments. He made those apportionments in the light of his three years' experience in Woodhouse and Rawson United, and they were quite fair, being, in fact, in favour of the industrial business. He brought out as the total debit side of the account for that year £44,556. He had included the head office expenses in proportions according to the space occupied by the different branches. His analysis of this balance-sheet and profit and loss account showed a loss on the industrial business of £24,603. His draft balance-sheet, which was submitted to the Directors, showed a loss of £15,000 on the whole of the business. He was not an expert in the valuation of stock, but he knew it was not right to take stock at the old value year after year. There was depreciation of stock in some cases,

Digitized by Google

but he contended that there should be depreciation all round. The stock and plant at Kidsgrove were very antiquated and greatly over valued. Money was spent in improving the plant, but he could not say to what extent. Witness upon various occasions suggested that the whole of the stock should be valued by an expert, and also that the auditors who audited the Manchester accounts, and went into the valuation of the stock there should also audit the accounts of the Cadby Hall works. His suggestions, however, were as a rule taken no notice of. He thought there was a good business if it had been properly managed. He attributed the loss to many causes. First, there were too many departments, all more or less cutting each other's throats and trading entirely on their own account. Then there was no guiding hand over the whole lot; and the works were scattered about all over the country, necessitating a large amount of money being spent in carrying them on. There was an increase in the turnover of the Company as time went on; but the profits did not increase. He had several discussions with the Managing Director as to the value put upon the shares of the different companies which they held, and he suggested that as they had not realised any large amount of Okonite stock or shares in the previous year, they ought to take those in at a lower value. He did not pretend to be a financier, nor did he base his opinion upon the merits of the inventions concerned in this and the Epstein case, regarding which he expressed the same opinion. The supply department had been selling a few Epstein accumulators; but there was no large public demand for them, and it was this fact which led him to suggest writing down the value. The way in which he would have treated that matter under the circumstances, the Company being brought out on the last day of their financial year, would have been to have simply taken the amount spent on the invention, and regarding it as a book debt. He would not have included anything as profit for that year upon that head, but would have held it in suspense.

By Mr. MUIR MACKENZIE: At the time, shortly after he joined the Company, that he found it was being conducted at a loss so far as the industrial business was concerned, he thought there should be a good future for the Company, but that it depended absolutely upon the management. He certainly believed there was a goodwill, but was astonished to find it put at so high a figure. That was, however, a subject upon which people might reasonably differ; so much depended upon personality. His opinion was that the goodwill would have been much more valuable but for the financial operations of the Company, for it rested mainly in the industrial part of the business, and people would not put so much faith in them in consequence of their conducting a financial business, as they would have done had they confined themselves to the industrial side.

By Mr. F. L. RAWSON: He could not say that the Directors were desirous of extending the industrial business in the sense of acquiring new works, but certainly they wanted to develop the resources of the works they had, and carry them on at a profit. It would take from two to three years before any large outlay on a business of that kind would become remunerative. Expenditure upon advertising, exhibitions, and catalogues, should show some return at a considerable period. He would be astonished to learn that the value of the time expended by him (Mr. Rawson) upon the preparation of the catalogue and price list for 1889, taken at a reasonable rate, would amount to £1,500. In November, 1891, they were anticipating a large increase of business, and there was a certain amount of new business of a nature requiring outlay before it could be carried out. Most electrical companies made big losses at the outset, or in entering upon new developments. He agreed that, owing to great competition, the profits on contracts were so small that they were swallowed up by the standing charges, and yet it might be necessary to keep up those standing charges in the hope of getting larger work in the following year. He was not, however, in favour of keeping up those standing charges to the full extent. The competition was more severe in their case than in that of others on account of their carrying on a dual business. If they tendered at the same price as other leading companies the others would always get the preference. Had the Champs Elysées work, for which they were negotiating, been carried out there would probably have been £200,000 worth of work done there. The Jensen bell works were closed when it was discovered that they were being carried on at a loss. The stoppage of the lamp business was undoubtedly a severe blow to the Cadby Hall Works. Attempts were made to bring about an amalgamation between the Epstein Company and another Company; but he did not know of any other steps taken to realise the shares in that Company. Mr. North, the manager of that Company, expressed himself very sanguine as to the prospects of success of the industrial business about the end of 1891. Witness could not say what it was that induced him (North) to express such an opinion; but it was a fact that about that time he approached Witness with regard to obtaining money for him without the knowledge of the Managing Director. This witness positively refused to do, and, as his suspicions were aroused, he began to look into matters with which North was connected, and found that there were certain irregularities, which he reported to Mr. Rawson. It was possible that North feared if he reported the true state of affairs in regard to the industrial concerns matters would be looked into and a discovery made of his irregularities. Mr. North had the absolute confidence of the Directors, and witness was never more astonished in his life than when he discovered what had been going on. Witness had always thought there was a possibility of turning the industrial business to good account, and when he was made manager said he would undertake that it should show a profit if all the debts were paid off, and he was given £15,000 clear, not to be interfered with for other purposes of the Company.

By Mr. H. G. RAWSON: His relations with Sir Rawson Rawson had always been most friendly. He had spoken frankly to Sir Rawson, who in return spoke frankly to him, with regard to the affairs of the Company. He believed Sir Rawson gave careful consideration to his suggestions, and discussed them at the Board meetings, but he could not distinctly remember any particular occasion when he took witness's view and advocated it in opposition to that of the Managing Director. Sir Rawson was indefatigable in the attention he gave to the business. When he suggested to the Board that it would be well if the Managing Director would repay the loan made to him, he was not aware of the circumstances attending that loan, nor of the arrangement made with regard to its repayment. He adhered to his statement that the fact of their carrying on a dual business acted prejudicially with regard to the industrial side of the business. Witness himself once had an interview with Mr. Preece, electrician to the General Post Office, and that gentleman told him plainly that he could never recommend the Company whilst it carried on such a business. Witness tried to remove what he regarded as Mr. Preece's misapprehension with regard to the nature of the financial business, and stated that the contract department was really anxious to develop industrial business, but to no purpose.

JOHN MUMFORD, a transfer clerk in the employ of the United Company, was examined as to the withdrawals prior to the allotment, but could throw very little light upon the matter. In reply to Mr. Pilling, he stated that 270 £5 vendors' shares were registered in his name, as the nominee of Woodhouse and Rawson (Limited), for the purpose of registration at Somerset House, and they were immediately afterwards transferred to the Limited Company. In response to a query by Mr. F. L. Rawson, witness said he (Mr. Rawson) was frequently at the offices of the Company into the small hours of the morning.

Sir RAWSON RAWSON was next called, and, replying to the Official Receiver, said he was elected a Director of the United Company on August 5, 1889. He was away in the country at the time the prospectus was issued, and had no part in the preparation or issue of it. He was not in any way interested in any of his son's companies prior to that, but he had been connected with another electric lighting company. He was appointed a member of the Works and Finance Committees, and he took an active part in the work of those committees.

The OFFICIAL RECEIVER: What was your view as regards the business? You have heard what Mr. Stutchbury gave as your opinion?

WITNESS: That is Mr. Stutchbury's recollection. I dissent from it in this respect: he made use of the term financial schemes, and I repudiate that word "schemes" entirely. From the beginning we took over the business of Woodhouse and Rawson (Limited). The principal business, which has been charged against them here is introducing new electrical inventions and working out the patents which they acquired. Now, that could only be done in three ways: first by working the patents or carrying out the inventions by the Company with its own capital, or by selling the patents, or by bringing out the patents through the instrumentality of other Companies formed to work them. It was clear that with our limited capital—too limited from the beginning—we were not in a position to work any number of new patents, or bring out the inventions ourselves. The question then was, was it most profitable to the shareholders of Woodhouse and Rawson United to sell the patents and divest ourselves of any further interest in these inventions, or to put them into the hands of companies from whom we might not only gain an immediate sum, but also a future interest in the working of the patents.

Did you or did you not say that you would in the future probably bring out 10 companies where in the past you had brought out one?—I have no recollection of having said anything of the kind beyond this, that, as from the beginning, as we stated in our first report—

Do you deny that you stated to Mr. Stutchbury that the Company would bring out 10 companies where they had brought out one in the past?—As so expressed, I do. My memory of it is this, as from the beginning it was stated by myself and the Directors, and by Lord Aberdare, that we could not make a profit of 15 per cent.

Will you point to one patent acquired by the United Company that you sold? You mentioned that it was a matter for your consideration as to whether you should part with those patents you had to different companies, or whether you would endeavour to work them yourselves. Have you throughout parted with one single patent which you had acquired?—I do not remember.

Is it not the fact that these companies you brought out were all companies the patents for which you acquired nothing after the Company was in existence? For instance, the Okonite, the Epstein, and so on?—The Okonite and Epstein we were working at from the beginning.

Those were not the patents I understood you to refer to as the patents you had acquired at the formation of the Company.

Mr. H. G. RAWSON: It is not suggested that they took over patents from the Limited Company for the purpose of developing them.

The OFFICIAL RECEIVER: Those patents you referred to were acquired from Woodhouse and Rawson (Limited)?—Some, and some were acquired afterwards. They came into our possession by purchase not only from Woodhouse and Rawson (Limited), but from others, Mr. Baker and others, and we took out patents after we were formed.

Can you point to a single patent that you sold?—Yes, the Elmore.

Did you ever possess the Elmore patent?—I cannot say now whether we possessed the patent. We possessed the right of disposing of Elmore's process.

In what way?—In whatever way we thought profitable.

What was the process?—The process of depositing copper by electricity.

What do you say the United Company acquired?—That privilege of disposing of the right of using Elmore's process.

I put it to you that this was merely an option to acquire shares?—It may be.

Do you call that an option to use this process? Is not that a great mixing up of financial and industrial?—You may call it so. We were interested in bringing out a most important process.

I put it to you that all you possessed was an option to sell certain shares in the Elmore Company?—That may be.

Did you go into the nature of the business of any of these Woodhouse and Rawson Companies after you joined the Board—take, for instance, the

Manufacturing Company ?—The Manufacturing Company was engaged in the manufacture of incandescent lamps, and I looked upon it that we had a patent——

Did you go into the accounts ?—Generally, not specially.

Were you aware that there was a very large loss ?—No, I was not. I was perfectly aware that immediately before the formation of the United Company a large sum had been spent by the Limited Company in the investigation of the value of several inventions which they then had in hand. Continuing, in reply to questions, WITNESS said he supposed he saw the document prepared by Mr. Baker showing the turn-over and the payments in connection with the Manufacturing Company for each month of the six months immediately preceding the taking over of the business by the United Company. At that time the Limited Company was devoting itself to the development of certain inventions which had been brought to its notice, and no profit could be expected from that expenditure at that time. That was one reason for the loss shown. Another reason was that the works at Cadby Hall had become disorganised. The attention of the Managing Director of the Limited Company—he did not know how far he was interested in the Manufacturing Company—had been devoted to trying to bring about the formation of a large electrical company, and this ultimately resulted in the formation of the United Company. To these causes he attributed the losses shown. He knew that since the Edison-Swan Company obtained judgment against them the losses began.

The OFFICIAL RECEIVER: Were you aware in 1890 that there was a considerable loss on the industrial business generally ?—No. The statement put before me by the accountant did not show a loss. I hear here for the first time that it is established that there was a loss in 1890.

Were you aware that the Manchester business showed a loss of £1,905 ?—I was not. Some of the branches showed a loss, and others did not. The statement to which I refer was the analysis of the accounts for 1890, which I sent to Lord Aberdare.

At all events, for the year to June 30, 1890, the gross receipts appear to have been £109,597. There was premium on shares, £4,050; Okonite profit, £37,235; Kensington Stores profit, £17,384; and the Elmore shares profit, £29,437. Those, I think you will agree with me, must be all treated as exceptional items ?—I do not know what you mean by exceptional items.

You could not expect to make another profit of £29,000 on Elmore shares the next year ?—Yes, we could. Not from the same articles, but from business of a similar nature. All this occurred in 1889 and 1890. You must remember the great depression which followed that, in judging of the action of men, and the valuations put upon patents at that time.

Mr. Registrar HOOD: You say you do not regard those profits as exceptional because you laid yourselves out for that kind of business ?—Decidedly. We told our shareholders we were going to do it. We took over the business of Woodhouse and Rawson (Limited), and that was the business of Woodhouse and Rawson (Limited) to acquire inventions and buy patents and bring out those patents.

The OFFICIAL RECEIVER: With regard to the Elmore Companies, you got that profit by acquiring an option from the Limited Company, and that, I put to you, was pretty nearly exhausted by this £29,437. So from that source you could not expect to make a profit on the next year ?—Yes, we could, because we had the American Elmore Company.

Did you hope to make £29,437 out of the American Elmore ?—No, but we expected to make £20,000.

You did not expect to repeat the Kensington Stores profit ?—Certainly not.

Or the Okonite profit ?—That might be repeated annually.

Not from Okonite shares ?—No, but from similar transactions.

This only leaves you, as the receipts on your industrial business, the amount of £21,491, as against an expenditure, exclusive of Mr. Rawson's commission, of £34,737. Those figures would not be very satisfactory ?—I do not see what right you have to exclude all our principal sources of profit and then say the expenses were in excess of the receipts.

It would not be very satisfactory to the shareholders to know that their industrial business was not paying ?—They were informed of it. They knew it.

The OFFICIAL RECEIVER read an extract from a speech made by the witness at a meeting of the shareholders, in which he said there was every prospect that "the success which had hitherto attended the Company would be maintained," and asked: Do you think that was possible, seeing the state of this industrial business ?—What I said then I meant. At that time we had a prospect of negotiating business which would have entailed as large a profit as that made in the first year.

Was there anything in the prospectus to lead people to believe that out of a gross income of £109,000, £88,000 would be earned in this exceptional manner ?—The prospect held out in the prospectus was of a dividend of 15 per cent. on the Ordinary shares, and of 8 per cent. on the Preference.

But how was that to be earned ?—That did not matter so that it was earned honestly. Our Articles of Association gave us unlimited scope, but we confined ourselves almost exclusively to matters connected with electrical inventions.

At this stage the Court rose, the further hearing being adjourned until Friday, the 20th inst.

Woodhouse and Rawson United (Limited) v. Jolin and Co.

In the City of London Court on Monday the plaintiffs sought to recover the sum of £8. 11s. 9d. for goods supplied to the defendants. It appeared that the claim was not in dispute, but the defendants raised a counter-claimfor goods supplied by them to the plaintiffs, for a larger sum. The goods which formed the subject of the counter-claim were supplied before March 10, 1893, on which day Mr. F. D. Leslie was appointed by the Court as Receiver of the plaintiff Company in an action by the debenture-holders, and in that capacity he was still carrying on the business of the Company, and he had sold the goods which were now sued for by the plaintiffs to the defendants. The question was whether the defendants were entitled to set up against the Receiver a claim which he could only prove against the Company, it being in liquidation. This was one of several cases which must of necessity come before the Court, and the people who were being sued were in each case setting up counter-claims.

The defence was that no notice of the appointment of the Receiver had been given until after the contract had been entered into. If the Receiver was not practically the same as the plaintiff's, what right had he to enter into the contract.

Mr. Registrar WILD, before whom the case was heard, pointed out that a Receiver for debenture-holders was different from a Liquidator in a winding-up. There might be a Receiver appointed by debenture-holders without the outside world knowing anything about it. Of course, if the Receiver were acting in the winding-up, the defendants would be supposed to know of the matter. As it was, how were the defendants to know whether they were dealing with the Receiver or with the Company.

Mr. HICKS, for the plaintiffs, admitted it was very difficult, but in this case the Receiver was appointed in open Court.

The REGISTRAR said that made no difference. He did not think there was any difference between a Receiver acting on behalf of debenture-holders and an ordinary Receiver in a partnership action. If there was a dispute between partners a Receiver was put in, and he went on managing the business, as was the case here.

Mr. HICKS pointed out that in a case of a Receiver for partners, he acted for two interested parties. The Receiver in this case was the secured creditor of the assets of the Company, and the defendants were trying to get at his (the Receiver's) assets. The defendants wanted to spring upon the Receiver the debts of the old Company, and the Receiver could not carry on the business if that were to be done.

The REGISTRAR said if the Receiver had dealt with the defendants in his capacity as a Receiver with notice to the defendants, then it would be a different matter. But as it was he must determine to entertain the counter-claim. He would adjourn the case so that the authorities on the subject might be looked up, and then the point could be argued before the judge, with a view to its going to appeal.

The case was therefore adjourned.

National Telephone Company v. Morris Brothers.

At the Sheffield County Court judgment has been given in this action, particulars of which have appeared in *The Electrician*.

The defendants are chemical manufacturers at Doncaster, with works at West Stockwith on the Trent, and the plaintiffs sought to recover £50 rent due for a private wire. There was a counter claim for £50 damages for alleged ineffective service of the telephone wire.

The JUDGE said the claim for rent was admitted, and therefore judgment would be entered for the amount. The counter claim, with which he had only now to deal, was for the damage alleged to have been suffered owing to the defective working and construction of the telephone. The damages were caused by delay in communicating between the works and the office of Messrs. Morris, which had caused delay in executing orders for goods, had put the defendants to additional expense for delivery, and had caused their customers to refuse payment; loss of time was also alleged in unsuccessful attempts to obtain telephonic communication. The contract entered into was that Messrs. Morris should pay £100 per annum in advance for a term of years for the use of a private telephone wire and three sets of instruments between the office at Doncaster and the works at West Stockwith. The conditions of the contract were that subject to the performance by Messrs. Morris of the conditions laid down, the Company would maintain the telephone in good working order. One of the conditions was the payment of rent in advance, and, in point of fact, it had always been in arrear. Another clause was, "In the event of the said wire or apparatus not being in good working order, the Company shall repair and restore the same at its own expense, and with all possible despatch, but the Company shall not be held responsible or liable to the lessee in damages or otherwise howsoever for any delay provided it uses every reasonable endeavour to restore the communication as speedily as possible." From the letters and evidence, it appeared that on numerous occasions the wire was out of order, caused by all kinds of accidents, such as the falling of branches of trees, shooting, rain, and the fumes from Messrs. Morris's works. In every case where a complaint was made to the Telephone Company it was at once acknowledged and attended to. He thought the Telephone Company had a right to complain of the way in which Messrs. Morris had brought the counter-claim. The particulars of the claim covered a space of nearly three years, and the claim was brought by the Company. It was very well observed the other day that in nearly all cases a counter-claim was the result of an after-thought, and until this action was brought Messrs. Morris never thought of claiming. When the claim did come, it was in the most unfair way a claim could come against a company. How could a company explain everything that happened to one particular wire during three years? The counsel for the defence relied somewhat on a letter written by Mr. F. W. Carr, who stated, "We guarantee that the communication between your office and works will be absolutely satisfactory to you, and that any repairs will be attended to at once." There was nothing to show that this gentleman had authority to bind the shareholders, and there was no consideration for this, as was the case in the contract itself. On the whole he thought the Telephone Company had performed their contract as well as such a contract could be performed, because the wire must be subject to sudden accidents of all kinds. They seemed to have remedied the causes of complaints as soon as they were mentioned, and, in his opinion, had taken a great deal of trouble in doing so. In more than one instance a clerk walked the whole length of the

Digitized by Google

wire—22 miles—to find out where the fault was. That was extreme carefulness on the part of the Company. He found a verdict for the Company.

Mr. ELLISON, for the plaintiff, asked for costs on the higher scale, and his HONOUR said Messrs. Morris had done very wrong in bringing the counter-claim as they had done, and he should grant Mr. Ellison's request.

Brasyer v. Harness and Another.

The further hearing of this case was resumed on Friday.

Dr. M'CULLY, recalled, was cross-examined by Mr. Witt. Asked as to the prosecution against him for libel, he said he had got two years' imprisonment on account of it, and he served the whole term. That was in September, 1887. It was about two years later that he went into Harness and Co.'s business. Asked about Harness's trusses, he said he knew nothing at all about Harness's truss or belts.

Letters was then read in which witness offered the solicitors to the prosecution to give them his assistance as a witness against the Harness Company.

Mr. FRANK DODD then read the cross-examination of Dr. Lewis Jones, M.R.C.S., given at the police-court proceedings against the defendants, with the object of showing that it was possible to have an electric current even in the unconnected belt.

This closed the evidence for the defence, and Mr. Witt proceeded to call evidence in rebuttal of the defendants' counter-claim.

The case was adjourned until Monday.

MONDAY, JULY 9TH.

On the hearing of this case being resumed,

Mr. COLYER, the plaintiff's solicitor, was further examined by Mr. Witt. When Col. Brasyer first instructed him the colonel was doubtful whether he should take civil or criminal proceedings, and after the *Pall Mall* articles he decided to take criminal proceedings as well as the civil.

Mr. ABINGER: Why was Dr. M'Cully selected for prosecution out of the 130 employés at Harness's?—Because he was the only one Col. Brasyer knew.

Mr. ABINGER: That is your only answer?—WITNESS: Yes; that was the reason. He thought that had all the witnesses for the prosecution —some 400—been called at the police court the result would have been different. He did not say that he thought there would have been a conviction, but he did think there would have been a committal.

Mr. GATEHOUSE, the editor of the *Electrical Review*, called, said he had been for 20 years an electrical engineer. He had never in any way been connected with *Science Siftings*, and had had nothing to do with the articles about Harness and Co. that had appeared in the *Pall Mall Gazette*. The connected belt did generate a very minute current of electricity depending upon the degree of moisture of the skin of the wearer. There was no such current in an unconnected belt. The highest current he had ever found in a connected belt was a $\frac{1}{100}$th of a milli-ampere. If the webbing of the belt became wet the current generated would flow round and round the belt, and not into the body. Where the zinc discs touched the skin the action upon it by the natural perspiration would create oxychloride of zinc, a poisonous salt, which would cause sores upon the skin at the points of contact. He had experimented with the Harness belts from 1892 up to now, and those experiments had confirmed his opinion that no current from the belt passed through the human body.

Mr. JELF cross-examined witness at some length, eliciting that the witness had for a long time taken a strong view against Harness's alleged curative system. His electrical experience did include the effect of electricity medically, in as far as testing Harness's belt, but it was true that that was not the form in which he was most conversant with electricity. He had heard Lord Kelvin say in his evidence in the Alabaster case that, in his opinion, the electric current from a connected Harness belt entered the body. The witness added that Lord Kelvin was then only expressing an opinion, as he said he had never experimented on the subject. Witness admitted that he had in his cross-examination in former proceedings said that where you obtained the chemical action he had described to-day, there would in all probability be an electric current present. He had never gone to Harness's to see the electrical appliances there, though he had had an invitation to do so. Mr. Lynd had written letters to the *Electrical Review*. Shown a letter of Lynd's in December, 1886, to Mr. Harness, he said it had been produced and put in during the police-court proceedings. In it Lynd did suggest to Harness the idea of the unconnected belts; but witness did not look upon Lynd as any authority on that point.

Prof. HORSLEY, called, said that in diseases of the nervous system the use by patients of something in which they believed went a long way in curing them. As regarded Harness's belt, a belief in its efficacy would assist a cure. That was called "suggestion." The origin of charms and amulets no doubt arose from this cause.

Mr. JELF objected to this evidence.

Mr. Justice CHARLES held it admissible.

Examination continued: These belts gave support and warmth to the body, and that alone in hysterical cases would be of benefit to the sufferer. He had seen Harness's belts produced by patients, but had never scientifically examined them. He had studied questions of electricity, and in his opinion the Harness belts had no effect at all on the human body. The resistance of the skin was so great and the current so feeble that the latter could not enter into the body, but would only irritate the skin, and might produce sores.

Mr. Avory cross-examined WITNESS: To have any therapeutic effect it was his opinion that the electric current must pass through the skin, and this was not the case. He did not believe that there were present at all times in the human body electric currents. Scientific men were not all agreed upon that subject.

Mr. WITT, after briefly re-examining this witness, said that closed the plaintiff's case.

Mr. JELF, addressing the learned Judge, asked if it would be convenient for his Lordship to state what would be the questions which he would ask the jury.

Mr. Justice CHARLES, in reply, said that he would ask the jury, first, as regards the issue in the action—(1) whether Harness or M'Cully had been guilty of the alleged misrepresentations, and whether Colonel Brasyer had been induced to part with his money to the defendant by reason of such misrepresentation; (2) whether Harness or M'Cully had been guilty of negligence in treating Colonel Brasyer.

Mr. JELF reminded his Lordship of his submission at the close of the plaintiff's case on the issue in the action, viz., that Harness, being merely the servant of the Company, could not be made responsible for another servant's negligence.

Mr. Justice CHARLES said he bore that in mind; but he thought, as he had said before, that there was some evidence to go to the jury that Mr. Harness—notwithstanding the fact that this business was carried on by a company—was the real head, and his the controlling hand, and not the Company at all. Referring to the issue raised by the counter-claim of the defendants, the learned judge said he should ask—(1) Did Brasyer honestly believe in the case which he laid before the police magistrate? (2) Did Col. Brasyer or his agents (the solicitors) take reasonable care and precaution to investigate the facts upon which the information was laid? (3) Was Col. Brasyer actuated by malice towards Harness or M'Cully? And should these gentlemen, or either of them, be entitled to succeed on their counter-claim, then what damages were they respectively entitled to?

Mr. JELF then proceeded to address the jury for Mr. Harness.

Mr. AVORY followed on behalf of Dr. M'Cully.

TUESDAY, JULY 10TH.

On the hearing of this case being resumed before Mr. Justice CHARLES, the learned Judge summed up. He said that there were two actions to be decided—(1) by Brasyer against Harness and M'Cully for false pretences and negligence; (2) by Harness and M'Cully against Brasyer for malicious prosecution. The plaintiff said that both defendants were parties to the issue of false and misleading advertisements, by which the plaintiff was led to present himself at 52, Oxford-street. M'Cully was not by name a party to the issue of these advertisements, and he was a servant in the service of the Company. Whether he was so implicated in the fraud, if fraud there was, as to be liable, was a question for the jury. Did the defendants represent that they were highly skilled in the treatment of the complaint from which the plaintiff was suffering? His Lordship read various extracts from pamphlets of the Company which had been put in, and said it was clear that Harness had described himself as a "consulting medical electrician." It was no exaggeration to say that he had no medical knowledge; he had studied in no medical school and under no doctor; he was in no sense a scientist. What was what he might call the "note of quackery?" Was it a profession that a single remedy would cure everything? His Lordship read a list of the ailments (including premature old age) said to be cured by the electrical treatment. Could any human being in his senses suppose that all those evils could yield to one thing? The learned Judge then dealt with the evidence at some lengths. With reference to the counterclaim, he pointed out that before the prosecution was begun Brasyer's solicitor, Colyer, had made himself acquainted with all the facts proved in this action, with the extraordinary conduct of the Medical Battery Company in the three actions ending in the spring of 1893. After explaining the law as to malicious prosecution, the learned judge left the following questions to the jury:—As to the claim—(1) Were Harness and M'Cully, or was either, and which of them, guilty of misrepresentations, and was Brasyer in consequence induced to part with his money? (2) Were both or either guilty of negligence in the treatment? As to the counter-claim—(1) Did Brasyer in the prosecution honestly believe in the case laid before the magistrates—(i.) as regards Harness; (ii.) as regards M'Cully? (2) Did Brasyer or his agents act with reasonable care in prosecuting inquiries before they instituted the case—(i.) against Harness; (ii.) against M'Cully? (3) Was Brasyer actuated by malice—(i.) against Harness; (ii.) against M'Cully? (4) What damages, if any, have Harness or M'Cully suffered? Clearly if any damages were due they would be substantial in either case.

The jury returned at 5.30. In answer to question (1), as to the claim, they found that M'Cully had made no misrepresentations; as to Harness they could not agree. In answer to (2) they found that neither Harness nor M'Cully had been negligent. With regard to the counter-claim, they could not agree with regard to any of the questions, or either of the defendants.

Judgment was given for Dr. M'Cully, on the claim, accordingly.

The learned JUDGE said he was prepared to hear further arguments if desired.

Mr. WITT undertook to decide before to-day as to whether he would ask for further argument.

Anglo-American Telegraph Company (Limited) v. Compagnie Française du Télégraphe de Paris à New York.

In our issue of the 29th ult. we gave a *résumé* of the long-protracted proceedings in the action brought by the English Company against the French Company, claiming damages for loss sustained in consequence of the rupture in 1887 of the "common purse" agreement made six years previously.

The final judgment of the Court of Appeal given on Tuesday, was, as was anticipated, in favour of the Anglo Company. The Court held that the P.-Q. Company should have sought the approval of the French Govern-

Digitized by Google

ment before breaking the agreement, failing which it acted on its own responsibility and at its own risk. But as it was evident by the Ministerial dispatch of May 21, 1891, that the French Government would not have given its consent to the fusion of the two Companies, the Anglo Company were only entitled to damages for any injury it might have sustained through the rupture for the period between December 31, 1886, and May 21, 1891. The Court was not able itself to assess these damages, and therefore referred the matter to MM. Flory and Verbeecque and a third person yet to be chosen, to determine the amount to be paid as compensation to the Anglo Company. The P.-Q. Company are to pay all costs up to and including this judgment, the question of further costs being reserved.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE.

With the next issue of "THE ELECTRICIAN" will be published as a Supplement (Gratis to Subscribers) a large sheet "Practical Wiring Chart."

TENDERS INVITED.—The Waterworks Committee of the Hull Corporation invite tenders for the purchase of land, buildings, wells, bores, pumps, engines, boilers, plant and works recently used at the pumping station of the Newington Water Company near Hull. The land is suitable for a variety of purposes, and especially so for manufacturing premises where a large quantity of water is required. The plant is in good working order. Tenders have to be in by July 20th.

——— The London County Council require tenders for the supply of engines, dynamos, motors, switchboards, &c., for the electric lighting station for the Victoria Embankment and Waterloo and Westminster bridges. Further particulars are given in our advertisement columns, and tenders must be sent in to the Clerk to the London County Council, Spring-gardens, S.W., before 2 p.m. on Tuesday, July 31st. Drawings may be inspected and specifications, &c., obtained at the Engineers' Department, County Hall, Spring-gardens, S.W.

——— The London County Council also invite tenders for the supply of boilers and fittings, steam and exhaust piping, surface condensers, and circular air-pumps and piping required for the electric lighting installation on the Victoria Embankment and Westminster and Waterloo Bridges. Tenders have to be in by 2 p.m. of the 31st inst.

——— The Corporation of Cheltenham invite tenders for the supply and delivery at their central depot of six 12-kilowatt and ten 6-kilowatt transformers. Specifications and other information can be obtained of the Borough Engineer, Municipal Offices, Cheltenham; and tenders have to be sent in to Mr. E. T. Brydges, Town Clerk, not later than 12 noon on the 24th inst.

——— The Carshalton Local Board require tenders for lighting the district with gas, oil, or other illuminant for twelve months from July 31st. Tenders have to be in by noon of the 18th inst. The lighting inspectors of Watlington (Oxon.) also require tenders for lighting by oil, gas, or other illuminant; and the Woking Local Board require tenders for lighting the Woking station and Maybury ward. Tenders must be in by the 18th.

——— The Tunbridge Wells Corporation invite tenders for the erection and completion of an electric light station and chimney shaft in accordance with the drawings prepared by Mr. Arthur Ardron, F.R.I.B.A. Tenders must be in by noon of the 27th inst.

TENDERS ACCEPTED.—The Queen's Hotel Company (Limited), Hastings, has received the following tenders for wiring required at the Queen's Hotel:—

Hastings Electric Light Supply Company (accepted)	£358	13	4
Spiers and Pond, London	510	0	0
Belshaw and Co., London	448	0	0
Strode and Co., London	343	0	0
Roger Dawson and Co., London	300	0	0
Raynes, Smith and Co., London	269	10	0
Fowler, Lancaster and Co., Birmingham	265	0	0

And for the electric light fittings and fixing the following tenders were received:—

B. Verity and Sons, London, W.C. (accepted)	£306	19	0
A. Hands, London	310	9	9
Hastings Electric Light Supply Company	345	18	4
Strode and Co., London	346	11	0
J. Barker and Co., London	411	0	0

——— In reply to the request for tenders issued by the Tunbridge Wells Town Council for machinery, &c., for the electric lighting scheme, 32 tenders were received. These were submitted to Mr. Preece, and the Electric Lighting Committee have recommended the following tenders for acceptance. This recommendation has been adopted by the Council:—

Babcock Wilcox (boilers)	£1,726	0	0
Johnson and Phillips (steam pipes)	277	10	0
ditto. (engines and dynamos)	2,778	13	0
ditto. (arc lamps and posts)	989	1	6
Crompton and Co. (switchboard)	428	10	0
ditto. (transformers)	832	14	0
ditto. (wiring of station)	46	0	0
Callender and Co. (mains)	2,306	12	0
Total	9,385	0	6

TENDERS ACCEPTED.—The St. Pancras Vestry have received the following tenders for boiler and engine-house, &c., at the central station buildings, King's-road, N.W.:—

J. O. Richardson, London, S.E. (accepted)	£7,117	11	1
Steed	7,187	0	0
Godson and Son	7,347	8	0
Pattinson	7,500	0	0
Munday and Son	7,536	17	7
Wilkinson Bros.	7,579	0	0
Mowlem and Co.	8,948	0	0

——— The tender of Messrs. B. Verity and Sons for wiring the Chelsea Town Hall has been accepted by the Vestry for the sum of £277.

——— The tender of Messrs. Jonah, Francis and Son, of Newport, has been accepted for laying down pipes in connection with the Newport electric lighting scheme.

——— The Wolverhampton Corporation have accepted the tender of Messrs. H. Willcox and Co. for the construction of the necessary works and buildings in connection with their electric lighting sub-stations for the sum of £372. 10s., and the tender of Messrs. James Oake and Co., of Alfreton, for the supply of condenser pipes for the sum of £115. 2s. 2d.

——— The Paddington Vestry have accepted the tender of Messrs. Dawson, Hammond and Co. for the supply and fixing of private telephone wires, and sets of instruments to connect the Vestry Hall, the Bridge House, and other wharves belonging to the Vestry.

TENDERS RECEIVED.—The London County Council have received the following tenders for the erection of a generating station in connection with the electric lighting of the Victoria Embankment and the Waterloo and Westminster bridges:—

Messrs. Kirk and Randall	£5,916
Messrs. Foster and Dicksee	£5,562

——— On Monday last the Ayr Town Council met to consider the tenders received for the electric lighting plant recently advertised for. After some discussion the following tenders were remitted to the Electric Lighting Committee. It will be seen from the list that by the acceptance of separate tenders about £900 will be saved over any tender sent in for the whole of the plant and work required. The lowest tender for the whole of the work represents £10,138, and the highest £16,991, but some of the lower tenders are not complete. The actual lowest tender by any one firm is £12,760. Mr. Hammond's original estimate for the contract was within £12,000, and by accepting the lowest tenders in each case the Corporation will expend £11,834:—

Boiler Plant.

Tinkers, Limited	£2,700	Yates and Thom	1,898

APPOINTMENT.—Mr. J. Bruce Crawford, London, has been appointed Clerk of the Works for the new electric light buildings for the Coventry Corporation. 106 applications were received.

APPOINTMENTS VACANT.—The Governors of the People's Palace, London, E., will shortly appoint for their evening classes a head of the electrical department, at a salary of £150. There are several other minor appointments shortly becoming vacant.

———— The Battersea Polytechnic announce a vacancy for an electrical engineer. Particulars can be obtained of the secretary of the Polytechnic up to the 18th inst.

———— An assistant master for physics and elementary mathematics, at a salary of £120 per annum, and an assistant master for physics and electrical engineering, at a salary of £120 per annum, are required for the Hull Municipal Technical Schools. Particulars can be obtained of Mr. J. T. Riley, D.Sc., Director of Studies, Town Hall, Hull, and applications have to be sent in by the 24th inst.

———— The South-West London Polytechnic require a Principal to undertake the direction of the whole educational work, the higher teaching in at least one department of science, and headmastership of day schools. The salary will commence from April 1, 1895, at £600 per annum. Other particulars will be found in our advertisement columns, and applications must be sent in by the 28th inst. to Mr. F. P. Murray, secretary to the Governing Body, 47, Duke-street, St. James's, from whom forms of application and other details can be obtained.

———— The Corporation of Derby require applications for the post of assistant engineer at a salary commencing at £2. 2s. per week. Further particulars are given in our advertisement columns, and applications must be sent in to Mr. J. E. Stewart, Engineer and Manager, Electric Light Station, Full-street, Derby, by noon of July 21st.

BANKRUPTCY.—A receiving order has been issued against the estate of Edward Percival Oliver, trading as Newington, Priddle and Co., electrical engineers, at 50, Great Sutton-street, Goswell-road, London, E.C. The first meeting of creditors will be held at the Bankruptcy Court, on July 23rd, at 12, and the bankrupt's examination will take place at the same place on August 10th, at 11:30 a.m.

LIQUIDATIONS.—A meeting of the shareholders of the Scottish Electric Supply Company (Limited) is to be held at 5, North St. David-street, Edinburgh, on August 14th, at 12, to receive the account of the winding-up.

SALE BY AUCTION.—Messrs. Wheatley Kirk, Price and Goulty have just issued a catalogue giving particulars of the fixed plant and machinery, loose plant and utensils, stock and stores, patterns and drawings, &c., to be disposed of by public auction, at the Vulcan Iron Works, Market-square, St. Neots, Hunts, on Tuesday, Wednesday, and Thursday next, at 10 for 11 o'clock. The machinery is in first-class working order and by well-known makers, and the stock includes new horizontal steam engines, exhausters, gas holders, wet and dry meters, &c., &c. Nearly 1,000 lots are included in the sale. The catalogue contains full particulars of the train service.

WARNING.—Just now the electrical trades seem to be especially marked out for attention by the swindling fraternity. Last week we received a note from Messrs. Edmundsons; and Mr. Menzies, General Manager of the Consolidated Telephone Construction and Maintenance Company, now sends the following:—"I would caution electrical firms and companies—especially electric lighting, as they appear to be his next happy hunting ground—to be careful of a young man who professes to be in a position to place large orders for distant parts of the globe. His ingenuity is above the average, but unfortunately has, in his travels, got somewhat warped, and after dealing with the familiarity of a Rothschild with figures reaching to thousands of pounds, and after giving Messrs. Glyn, Mills, Currie and Co. as a reference, he wishes to know where he can get some lunch, as he is a stranger in London; and, finally, he winds up, or did in my case, with the information that he has lost his pocket-book! To me, he had come from New Zealand; his name was Harold Stannard; his address, the South-Western Hotel, Southampton; and the railway company he and his father represented was 'The Napier and Wellington.' Neither at the address given nor at Messrs. Glyn's is he known, and I am informed by a legitimate New Zealander that there is no railroad company called by that name."

SHIP LIGHTING.—The Acme and Immisch Electric Works have just completed a combination engine and dynamo plant for a ship in course of construction for the Manchester Ship Canal traffic. The firm have also in hand a 150-H.P. mining plant for South Africa.

IGNITION TUBES.—The Indestructible Ignition Tube Syndicate (Limited) notify that a reduction of 30 per cent. has been made in the price of these tubes.

NON-MAGNETISABLE WATCHES.—Messrs. S. Smith and Son, the well-known London manufacturers of accurate non-magnetisable timepieces largely used by electrical engineers, have just issued a "Guide to the Purchase of a Watch." This is a well-illustrated and admirably got-up treatise on all varieties of timepieces, and contains information which is of considerable interest to the electrical profession. The firm make specialties of their non-magnetisable watches and chronographs.

ELECTRIC CONSTRUCTION COMPANY.—In view of the difficulty experienced by many of the employés of this Company in obtaining suitable residential accommodation, the Directors have decided to erect on a portion of their Bushbury property houses for their workmen. It is stated that 20 houses are to be at first erected, and that subsequently the number to be built will be limited only by the demand.

MESSRS. WALTER T. GLOVER AND CO.—This firm have recently opened new offices, warehouse, staff dining-rooms, &c., in connection with their cable works at Springfield-lane, Salford. Mr. Edmunds, the principal, gave a supper and entertainment to his staff of employés on the occasion of the opening ceremony, to which nearly 400 sat down. In the course of his remarks to the staff, Mr. Edmunds pointed out how satisfactory the growth of the business had been, and the necessity of individual care on the part of all employed by the firm in giving particular attention to every detail, however small, in the preparation of the apparatus and material for which the firm had attained credit in the past, and looked forward to even greater credit in the future. In addition to the added offices, &c., the staff have now been provided with new dining-rooms, new lavatories, and cooking and heating arrangements which will materially add to their comfort. The structural arrangements have been carried out under the direction of Mr. Nodal, architect.

MESSRS. SIEMENS AND HALSKE AND THE ALLGEMEINE ELEKTRICITÄTS-GESELLSCHAFT.—It may not be generally known that the Allgemeine Elektricitäts-Gesellschaft and Messrs. Siemens and Halske, both of Berlin, have since 1883 worked in conjunction with one another. The agreement under which this arrangement has been carried out has still three years to run; but by mutual consent has been annulled. At a recent meeting of the Board of the Allgemeine Elektricitats Gesellschaft the communication was made that the Company had terminated its contract with the firm of Siemens and Halske. In consideration of the present termination of the contract, the A.E.G. pays to Siemens and Halske an indemnity which somewhat exceeds £30,000. Still, according to the agreement now come to, the A.E.G. has the prospect of receiving back from Siemens and Halske at any rate a portion of the above indemnity in the course of time. Under the contract now rescinded the construction and running of central stations, both in Germany and abroad, were to be carried on jointly by the two firms, while in the case of isolated plants the limits restricting the expansion of the manufacturing activity of the Company itself were removed; moreover, an agreement was come to about the prices for glow lamps. Messrs. Siemens and Halske have been relieved from the obligation of giving the A.E.G. the refusal of all concessions which they acquired. A new agreement has been made controlling the supply of cables, which will, it is considered, be advantageous to the A.E.G. The termination of the contract between the two parties has been amicably carried out, and is considered to be advantageous to both.

MESSRS. RUSSELL AND CO.—We have received from this firm of manufacturing electrical engineers and contractors, a newly-issued complete illustrated catalogue of electrical machinery. The catalogue is well printed, consists of over 200 pages of descriptive matter, and can be readily consulted for every variety of plant and apparatus required in electric light and power installations.

Digitized by Google

Pollard Glow-Lamp.—Mr. H. L. Merritt, of the Boston Incandescent Lamp Company of Boston (Mass.), is now in London and is seeking to introduce the Pollard glow-lamp in this country. The Pollard lamp, by avoiding the use of platinum leading-in wires, may be expected to have some attraction for manufacturers.

"The Journal."—Part 113 of the *Journal* of the Institution of Electrical Engineers is now ready, and contains a full report of the discussion on Mr. Crompton's Paper on "The Cost of Electrical Energy," and also a Paper by Mr. H. D. Wilkinson, "Notes on the Electrical Tramway System of the United States and Canada."

Catalogues and Price Lists.—We have received from Messrs. W. T. Glover and Co. a complete set of their various catalogues and price lists, which the trade can obtain on application either at Salford or to the London office, 39, Victoria-street, Westminster, S.W. The list includes wires and cables, dynamo and transformer specialities, Glover's patent armature bars, Trotter's wire gauge, Glover's jointing apparatus and materials, patent cable suspenders, &c., &c.

———— Messrs. Drake and Gorham send us an advanced copy of their revised catalogue. Every effort has been made to include in the new catalogue only such information as is likely to be of service and to be easily understood by those contemplating country house lighting and the putting in of electric lighting plant. The catalogue includes information that it is frequently difficult to obtain in such publications, such as the brake horse-powers which can be economically and safely obtained from the different sizes of engines. Messrs. Drake and Gorham claim that the figures given are reliable. The various price lists have been carefully revised, including that of the D.P. batteries ; the illustrations are confined to apparatus actually in general use ; and shippers will find the catalogue of value, as care is taken to set out in detail the necessary plant and apparatus for installations of various sizes.

Agency.—Messrs. Crosier, Mills and Co., have been appointed agents on the North-East coast for Messrs. Holden and Brooke (Limited), of Salford, and are making a display of injector and other steam specialities at Collingwood-street, Newcastle-on-Tyne, where also they invite inspection of a number of labour-saving devices.

Annual Outing.—The *employés* of Messrs. Rashleigh Phipps and Co. held their annual excursion on Saturday last, a gathering considerably in excess of previous years journeying to Brighton, and passing a pleasant day.

Barnet.—Messrs. Joel and Co., who have already had some experience in the lighting of this district, have notified the Local Board that they intend applying for a Provisional Order for the Barnet District Electric Supply Company. The matter has been referred to the Electric Lighting Committee.

Bath.—Notice has been received by the Corporation that the City of Bath Electric Lighting Company intend applying for a Provisional Order to supply electric current within the area of the city. This power the Company now hold under a Board of Trade licence, which restricts them to a certain area, and which gives the Corporation power to purchase the works at the end of seven years from the date of the licence. The matter has been referred to the Electric Lighting Committee for consideration and report. The date of the Company's licence is 1890.

Bedford.—A Local Government Board inquiry has been held by Major-Gen. Crozier in respect to an application of the Bedford Corporation for sanction to borrow £12,000 for its electric lighting scheme. Opposition was made to the proposal by Mr. W. B. Jessop on behalf of the Bedford Electric Lighting Company on the ground that the ratepayers should be acquainted with the total cost of the complete scheme before money was borrowed.

Bristol.—The Local Government Board have sanctioned the application of the Corporation for powers for borrowing £24,650 additional capital for electric lighting purposes. This will enable the Electrical Committee to clear off existing liabilities, and to make several extensions.

Burnley.—Notwithstanding that only about half of the promised subscribers to the Corporation electric lighting scheme have carried out their promises, nearly 5,000 incandescents are now in use in the district. This is considered by the authorities to be an excellent start, and additional applications are being received, which will shortly exceed the capacity of the plant at present installed. The plant is giving every satisfaction in its working.

Church and Chapel Lighting.—The Congregational Church at Castlegate, Nottingham, is now lighted electrically. The church has been connected-up with Messrs. Perry's factory in Stanford-street, where electrical plant is provided. The installation work is being carried out by Messrs. Danks and Co. It is intended ultimately to take the current from the Corporation mains.——The choir at Bristol Cathedral is to be lighted by electricity.

Commissioners of Sewers.—The Streets Committee have considered applications received for the appointment of electricity works inspector, and have resolved to submit for ultimate selection the following names :—T. A. B. Carver, B.Sc., C.E., G. Gerhardi, jun., and A. A. Voisey. The final selection will be made on Tuesday next.

Cork.—Mr. T. G. Fraser has given notice to the Corporation of his intention to apply for a Provisional Order for lighting the city by electricity.

Country House Lighting.—Under the superintendence of Mr. A. A. C. Swinton, Messrs. Edmundsons (Limited) are lighting Elveden Hall, Suffolk, recently purchased by Lord Iveagh. About 500 incandescents will be used. The plant consists of steam engines and dynamos with battery of accumulators.

Darlington.—The Town Council have referred an application from a number of the inhabitants of the Borough for the supply of electric light to a sub-committee for consideration.

Dover.—The charge for electric current has, we understand, been fixed by the Dover Electric Light Company at 8d. per unit, with a minimum charge of 13s. 4d. per quarter,

Fareham.—The proposal of the Local Board to purchase the Fareham Electric Light Company's undertaking does not apparently meet with the unanimous support of the ratepayers, and at the last meeting of the Board considerable opposition was manifested. After an exciting debate the Chairman announced that the contract for the purchase of the undertaking was not yet completed, and must be deferred for consideration at another meeting.

Folkestone.—Mr. Councillor Baker's scheme for the electric lighting of Folkestone is to be presented to the Town Council on the first Wednesday in August. Printed copies are to be sent to each of the members of the Council.

Geelong (Victoria).—The Crompton Electric Supply Company of Australia have submitted estimates to a sub-committee appointed by the town of Geelong and adjoining boroughs, for the electric lighting of the several districts. The Company's proposals have been accepted, subject to a report to be presented by Mr. Ellson, the electrical engineer, to the Mayors of the districts concerned.

Grasmere.—The Local Board have had official intimation from the Windermere and District Company of the Company's intention to apply for statutory powers for supplying current within the Grasmere district. The subject is to be discussed at a future meeting of the Board, the opinion being expressed that the Grasmere authorities are in a favourable position for themselves supplying electric current to the district.

Halifax.—About twelve months back the various rooms and decorations of the Masonic Hall were overhauled at considerable expense. It has now been decided to light the Hall throughout by electricity, which will save the heavy expense of redecorating after a short period. The work has been entrusted to Messrs. Walter Emmott and Co., of Halifax.

Hammersmith —The Electric Lighting Committee of the Vestry have received a report from a sub-committee stating that they have not yet been able to go fully into the report of the Vestry's engineers concerning the electric lighting question. The Committee recommend that applications should be made to the Board of Trade asking for an extension of time for a further two years for the compulsory carrying-out of the electric lighting Order.

Hartlepool.—At the last meeting of the Town Council it was decided to apply for a Provisional Order for electric lighting purposes, which was estimated to cost about £300.

Harrow.—A ratepayers' meeting has been held at the offices of the Local Board to discuss the electric lighting question. The Town Clerk gave a *résumé* of the steps that had been taken by the Local Board in the matter, commencing with the year 1888, when Messrs. Crompton and Co. sent in an estimate for lighting the town by electricity. This scheme was not carried through. In 1893 Messrs. Joel and Co. gave notice of their intention to apply for a Provisional Order for lighting the district, and the Local Board themselves decided to apply for a Provisional Order. The Board had considered the matter, and had come to the conclusion that if it were worth the while of a private company to apply for powers, then it was only right for the Local Board to consider the subject and keep the lighting of the district in their own hands. It is probable that another meeting will be held to discuss the subject shortly.

Helensburgh (Scotland).—The Scottish House-to-House Company has given notice to the authorities of its intention to apply to Parliament for an electric lighting Provisional Order for supplying electric current to this district. The Police Commission have decided to oppose the application.

Ilfracombe.—The Great Western Electric Lighting Company have given notice of their intention to apply for a Provisional Order to supply electric current to Ilfracombe.

Islington.—The Vestry have approved the recommendation of the Special Electric Lighting Committee with regard to the accept-

Digitized by Google

ance of the designs for the electric lighting station sent in by Mr. Tiltman, as mentioned in our last issue, subject to the approval of the London County Council. The Vestry have engaged Mr. Tiltman as the architect to superintend the erection of the works, and have decided to advertise for builders and to proceed as soon as the County Council's approval has been obtained.

KEIGHLEY.—It has been decided by the Town Council to call a special meeting to authorise an application to the Board of Trade for powers to supply electric current within the Corporation's district.

KENSINGTON.—The Vestry, having discussed the question of an increase in the salary of Mr. Philip Monson, the Vestry's lighting engineer, have decided that an increase shall be given from £300 to £330 per annum. Additional duties have recently been undertaken by Mr. Monson in the supervision of overhead wires, electric lighting mains, &c. Permission has been given to the House-to-House Company and to the Kensington and Knightsbridge Company to extend their mains to Redcliffe-gardens and a part of the Fulham-road, and to Stamford-road, Kensington, respectively.——The Commercial Electricity Supply Company (Limited), recently formed, has given notice of its intention to apply for a provisional order to supply electricity in portions of Kensington parish.

LANCASTER.—The Board of Guardians are to be asked at their next meeting to give their consent to the application of the Morecambe Electric Lighting Company for permission to carry out their contract with the Lighting Inspectors at Sandilands.——The Windermere and District Company are about to apply for statutory powers to supply electric energy within the Lancaster district.

LAMBETH.—Notice has been given to the Vestry by the St. James and Pall Mall Electric Light Company, of its intention to apply for a Provisional Order to supply electric current for public and private purposes within the borough of Lambeth.

LARNE.—A heated discussion took place at the last meeting of the Town Commissioners on the electric lighting question. The principal business before the Commissioners was the signing of an agreement with the liquidator of Messrs. J. E. H. Gordon and Co. for the lighting of the town for three years from August 15th next. Under the contract 11 1,700-c.p. arcs, 6 32-c.p., and 66 16-c.p. incandescents are to be used. The dispute which arose was as to a penal clause, and after much discussion this was added to the agreement, which was then approved.

LONDON COUNTY COUNCIL.—At the adjourned meeting of the Highways Committee on Tuesday last, a motion was carried that designs should be obtained for the electric lamp standards to be erected on the Victoria Embankment, the Highways Committee to take the necessary measures for the purpose, and to advise the Council what premium should be offered for the best design. It was suggested that the President of the Royal Academy be asked to adjudicate on the designs when they are sent in.

MONTROSE.—The Town Council have been notified by the Northern Electric Supply Company, of Aberdeen, of their intention to apply for a Provisional Order to enable them to supply electric current to the Montrose district.

MULLINGAR.—The Irish Electrical Supply Company will shortly apply for a Provisional Order for lighting this district by electricity.

NEWCASTLE.—The Town Council have agreed to the expenditure of £470 for installing the electric light at the Newcastle Town Hall.

OBAN.—A number of prominent tradesmen in this district are introducing the electric light into their premises.

PADDINGTON.—The Vestry have decided to obtain the information asked for in a requisition from a number of prominent ratepayers referred to in our last issue.

PRIVATE BILLS.—The Bill conferring further powers to acquire lands, &c., on the Charing Cross, Euston and Hampstead Railway Company has passed through the Committee stage in the House of Lords. In the House of Commons the Crystal Palace and District Electric Supply Company's Bill, for extending their system, has been passed, and schemes under which Messrs. Crompton and Co., and the Holloway Electricity Supply Company, are entrusted with similar powers in Chelmsford and Guildford respectively have reached their third reading.

PROVISIONAL ORDERS.—The Clonmel Provisional Order, which has already passed the Upper House, has now passed through the Commons, and is reported for third reading.——The Plymouth Provisional Order has been read a third time and passed.——The Monmouth Provisional Order, which has passed through the Lords and Commons, has been referred back, in order that the compulsory and other areas shall be certified.——The Chesterfield Provisional Order has received the Royal Assent.——The Yeadon Local Board's Provisional Order has passed the Committee stage of the House of Commons.——The Provisional Order applied for by the Wakefield Corporation has passed the Committee stage of the House of Commons.——The Aberdare Electric Lighting Provisional Order, which has passed the Upper House, has been reported for third reading in the House of Commons.——The Order applied for by the Birmingham Electric Supply Company has passed through Committee of the Commons.

RAMSGATE.—The Town Council have decided to give notice of opposition to the Brush Provincial Company's application for a Provisional Order to light the district by electricity.

RUGBY.—The Rugby School Electric Lighting Company are making considerable extensions, and have now connected up the new science department, lecture-rooms, &c.

SALISBURY.—The Town Council have instructed the General Purposes Committee to expend a sum not exceeding £50 in obtaining the services of an electrical expert, to advise the Council in electric lighting matters.

SCARBOROUGH.—The Electric Supply Company, which has now been in operation nine months, reports an equivalent of over 9,000 8-c.p. lamps connected to its mains. Messrs. C. A. Parsons and Co. have on order from the Company a turbo-alternator to give 75 kilowatts complete with condenser.

SHEFFIELD.—It is proposed to extend the electric lighting mains to the Broomhill and Ranmoor districts, and the plans have been approved by the Highway Committee of the Corporation.

SHOREDITCH.—The Vestry are memorialising the Board of Trade for an extension of time in connection with their electric lighting scheme. The question of the appointment of an electrical engineer was deferred.

STEALING.—James Brindley, a wireman, in the employ of the Telegraph Construction Corps, was summoned at Birmingham for stealing 50lb. of wire belonging to the Postmaster-General, and was sentenced to two months' hard labour.

SUNDERLAND.—The brewery of Messrs. C. Vaux and Sons, in Castle-street, has just been fitted throughout for the electric light by Mr. R. Vaux, engineer, of Bedford Works, Sunderland, to the specification and under the superintendence of Mr. G. W. Lummis-Paterson, of Newcastle-on-Tyne. The plant includes an Otto gas engine, a Taunton dynamo, D.P. accumulators, a 3,000-c.p. Crompton-Pochin arc lamp, and about 200 16-c.p. incandescents.

TAUNTON.—The Corporation Electric Lighting Station was inspected last week by Dr. Fleming, who, at the request of the Electric Lighting Committee, came down to examine the results of the improvements and alterations which had been made at his suggestion. When the Corporation took over the station of the Taunton Electric Lighting Company last September Dr. Fleming was invited to advise the Corporation. He reported that it would be necessary to begin laying the mains underground, and that certain additions and extensions to the station plant were absolutely necessary. He at once drew out a scheme for the formation of transformer sub-centres, and the first of these centres is now complete. In the central portion of the town a secondary circuit has been laid down, consisting of a ring main of triple concentric Fowler-Waring cable. This is fed by three feeders proceeding from a transformer station under the municipal offices. This station is provided with two 30-kilowatt Thomson-Houston transformers. All the house transformers in the centre of the town have been removed, and the customers jointed on to the secondary distributing main. Arrangements are being considered for the formation of other sub-centres. In the station a small Thomson-Houston 30-kilowatt alternator, supplied by the Laing, Wharton and Down Construction Syndicate, has been put down, which is driven by a 50-H.P. Bumsted and Chandler engine. This alternator does the light-load lighting. The boiler plant has been increased by the addition of a 105-H.P. Davey-Paxman Economic boiler. The steam piping, formerly in a very unsatisfactory condition, has been remodelled. Steel drums have been erected over the Babcock and Paxman boilers, and cross-connections made, so that any of the boilers can be put into connection with the engines. The Paxman boiler is primarily intended to work the arc lighting plant, but it supplies steam also for the Bumsted engine when that is doing the light load. The whole of the erection of the steam piping and the other alterations as suggested by Dr. Fleming in his reports, have been carried out by the Borough Surveyor (Mr. James Smith), and the Borough Electrical Engineer (Mr. Harold Couzens). The Electrical Committee have expressed themselves as very much pleased with the results of these changes in the plant. After making his inspection, Dr. Fleming was entertained at dinner by the Electrical Committee, the Chairman (Mr. W. Potter) being supported by the Mayor (Mr. Alderman Van Trump), Mr. Alderman Chapman, the Town Clerk (Mr. T. Meyler), the Borough Surveyor, Mr. Massingham, Mr. Newton, and others interested in the electric lighting of Taunton. Dr. Fleming reported fully to the Taunton Town Council on the following day as to the effects of the recent improvements and the probable direction of future extensions. Since the Corporation took over the station there has been a considerable increase in the number of customers, and there are now the equivalent of 3,348 8-c.p. lamps connected to the circuits. The Fowler-Waring cables and the electrical and engineering plant and apparatus generally have given the fullest satisfaction.

Digitized by Google

TORQUAY.—The Electric Lighting Committee has recommended the Town Council to retain the electric lighting powers conferred by their Provisional Order in their own hands, but for the present it is desirable to await the development of the scheme relating to the refuse destructor.

TUAM.—The Irish Electrical Supply Company have notified the Town Commissioners of their intention to apply to Parliament for powers to supply Tuam with electric current for lighting and power purposes.

TUNBRIDGE WELLS.—The tenders accepted by the Town Council for machinery, &c., for the electric lighting scheme will be found in a previous column. It will be seen that these are well within Mr. Preece's estimate, and that the outlay on the first portion of the work will not exceed the amount specified by the Electric Lighting Committee. It is expected that the tender for the erection of the buildings will be accepted at the Council's next meeting.

WALSALL.—A Local Government Board inquiry has been held in reference to the application of the Corporation for powers to borrow £22,000 for electric lighting purposes. It was stated that the estimated rateable value of the town was £151,210. The area of supply is the whole of the borough, which is of a scattered character. The Town Clerk said that there had been no application by any person or company within the area to provide electric current in the district. It was probable that ultimately the town would be called upon to supply the large district of Bloxwich, lying north of the borough. The Corporation's scheme had been submitted to the Board of Trade, and had received its approval.

WALTHAMSTOW.—It is stated that a movement is on foot to establish a local company to undertake the introduction of the electric light.

WEST BROMWICH.—A deputation from the Town Council has inspected the system of overhead electric traction in operation on a portion of the South Staffordshire Tramway Company's lines, with a view to sanctioning an extension of the branch from Darlaston to Handsworth.

WEYBRIDGE.—At the last meeting of the Lighting Inspectors a copy of a letter, sent by the Weybridge Electric Supply Company to the Board of Trade in reply to an inquiry regarding the placing of the electric lighting wires underground, was deferred for further consideration at a later date.

WHITEHAVEN.—The Town and Harbour Trustees have discussed a recommendation of the Electric Lighting Committee that application should be made to the Local Government Board for further borrowing powers on electric lighting account. Mr. Dees stated that the original powers allowed for £14,000 to be borrowed, and the work done under the original contract had only cost £12,295, or £1,700 less than the original estimate, but in carrying out extensions from time to time additional works had been sanctioned, which were not included in Dr. Hopkinson's original scheme; for instance, 43 arc lamps more than was at first provided for had been erected, the result being that up to the present time £15,494 had been expended. The amount of current supplied and work done generally in connection with the electric lighting scheme were as much as the present plant could cope with, and it was therefore desirable that an extra pair of engines should be provided, and it was consequently proposed that powers for borrowing a further £5,000 should be asked for. It was pointed out that the electric light was already a great success, and that in the near future a large profit would be derived from the supply of electric current. Mr. Jacques, a member of the Trustees, stated that he found in actual use that the electric light had proved to be in his case cheaper than gas.

WINDERMERE.—The Windermere and District Electric Lighting Company have given notice of their intention to apply for a Provisional Order for lighting this district by electricity. The Local Board some years ago obtained the necessary powers, but the time for working has expired. The Gas and Water Committee have the matter under consideration.

WOOD GREEN (LONDON, N.).—The Local Board have discussed an application of the Tottenham and Edmonton Electric Light and Power Company for sanction to apply to the Board of Trade for power to supply the district with electric energy. It was decided by the Board to first of all ascertain the names of the gentlemen forming the Company before any decision was arrived at.

WORCESTER.—It has been decided that the Watch Committee of the Corporation shall organise an exhibition of electrical appliances, &c., in the Public Hall, in October next, by which time the Corporation will be in a position to supply electric energy to private consumers. It was pointed out that by holding such an exhibition those citizens who were at present in doubt as to the advisability of putting electric light fittings into their premises would be enlightened, and would be in a position to select from the exhibits of the leading electric light fittings and apparatus makers, who would doubtless take the opportunity of displaying their wares for their own and the public benefit.

COMPANIES' MEETINGS AND REPORTS.

Eastern Telegraph Company (Limited).

The forty-fourth half-yearly general meeting of the Eastern Telegraph Company was held yesterday (Thursday) at Winchester House, Old Broad-street, under the presidency of Sir John Pender, G.C.M.G., M.P.

The SECRETARY (Mr. George Draper) having read the notice calling the meeting, the report of the Directors was taken as read.

The CHAIRMAN stated that the gross revenue for the half-year under review—to March 31st last—had been £389,314, being an increase of £16,461 as compared with that of the corresponding period of 1892. Analysing the message receipts from various sources, they found very little difference between the figures of last year, although there was an increase of about £4,000 in the Trans-Indian traffic and a small increase in the Cape traffic. The new cable of the South African Company to Seychelles and Mauritius was working satisfactorily, and that Company was now receiving a subsidy from Her Majesty's Government at the rate of £28,000 per annum. The results, so far as they had gone were fully up to their expectations. The principal increase in the gross revenue was due to their having received £29,500 from their investment in the shares of the Eastern and South African Company, as against £17,700 in the corresponding period; but, although there was an increase in the amount received this half-year, it was due to their having decided to pay the bonus at the end of the financial year, instead of half-yearly as formerly. The total amount received for the year ended March 31, 1894, was the same as that received in 1893. The total ordinary expenses for the half-year ended March 31st last amounted to £102,219, as against £102,499, or a decrease of £280. The working expenses at the stations had been £76,642 in the past half-year, as against £79,926, or a decrease of £3,284. The principal decrease was in stationery and printing for stations. Several other items also showed a substantial reduction, while in others there had been an increase. The principal item under the latter head was in salaries and wages of their staff at stations. This was due to the operation of the scheme to provide a regular scale of promotion to the superintendents and the other members of the staff. Travelling expenses also showed an increase of £398. This was an item which must necessarily vary and depend in a great measure on the number of men home on leave after serving the specified number of years abroad. With reference to other items shown separately on the revenue account, there was an increase in maintenance ships' reserve fund of £2,755. They had done very little work for foreign Governments and other telegraph companies this half-year, so that the full charge for depreciation on the ships was borne by themselves. Full provision had been made for depreciation on their spare cable, and the currency balances at stations had been written down to their actual sterling value on March 31st last. Expenses attending repairs and renewals of cables had amounted to £49,660, against £32,533, or an increase of £17,127. They had been at work on their own cables, with the exception of a small repair for the Spanish Government, so that credits derived from foreign Governments and other telegraph companies were small as compared with the same period of 1893. They had completely overhauled the steamship "Chiltern," and fitted her with new triple expansion engines and boilers, cable tank, &c., and had applied £18,000 in reduction of same out of the maintenance ships' reserve fund, which, however, remained at the substantial figure of over £53,000. They had at present three ships laid up in London; but, as he had often told them before, and as he now repeated, they were better pleased when their ships were idle, unless they were at work for other people. After providing the usual amount for interest on debentures, debenture stock, and Preference shares, they were able to propose the usual final dividend of 1¼ per cent. and bonus of 1½ per cent., making, with the interim dividends already paid, a total distribution of 6½ per cent. for the year ended March 31, 1894, and to carry the sum of £110,000 to the reserve fund, against £88,000 in the corresponding period of last year. They had also applied a further sum of £53,316 from reserve fund in reduction of the cost of the Aden-Bombay No. 3 cable and other capital expenditure, so that their capital expenditure on account of cables, &c., remained, as it had done for many years, at the same figure. Meantime they had greatly strengthened their position by duplications and in other ways, and had in this manner greatly increased the market value of their property. The total amount applied out of the reserve fund now amounted to £1,345,644. They had added to their capital investments £55,660 in the shares of the Europe and Azores Company. He had already explained to them that that Company was formed to lay a cable from Lisbon to the Azores, bringing those islands into direct telegraphic communication with their general system. In consideration of carrying out this work they had received an extension of their exclusive rights in Portugal, which in a great measure would recoup them for having made this investment. They had not anticipated that the Europe and Azores Company, so long as the cable only reached as far as the Azores, would give much return on the capital invested; but there were other considerations in the concession which might shortly be fulfilled, and he had no doubt that when the matter was fully developed, the Eastern Company's position would be considerably improved by being associated with this latest development of submarine telegraphy. The fact that they were paying the usual dividend and carrying £110,000 to the reserve fund was no small indication of their continued success. He had had a great many years' experience of commercial life, and he could assure them that he had never known such a prolonged term of depression as had existed, not only in London but thoughout the world. There was, however, he had no doubt, a better time coming. The Colonies had plenty of room, and they might depend upon it that the colonists' energies would not long lie quiet. When they became energetic again there would be a great response in

Digitized by Google

London, because, after all, a good deal of the money had to come from London. When the revival took place times would be good for their submarine telegraph system. Six months ago he stated that the Eastern and South African Company, in which the Eastern Company were the largest shareholders, had completed the Seychelles-Mauritius cable. That was a great work, and a very important addition to their system. The Azores cable had also attracted a good deal of attention, and it was now in their hands. Submarine telegraphy had become an important factor with all Governments, as was evidenced by the recent conference at Ottawa, at which representatives from this country and from the whole of the British Colonies were present. The principal question discussed at the Conference was the Pacific cable, and he was pleased to say that the conclusion arrived at on this matter showed judgment. A resolution was passed that soundings were to be taken, and that at the proper time the cable was to be laid. If it ever was laid the shareholders might depend upon it that those who had the most experience of cables would have a finger in the pie. The success which had attended their working during the last 25 years had been such that no great enterprise could be undertaken without their being consulted in some way. Their relations with all the Governments were most satisfactory. Next week they were going to celebrate the 25th anniversary of submarine telegraphy. He concluded by moving the resolution.

The VICE-CHAIRMAN (the Most Hon. the Marquis of Tweeddale) seconded the motion.

Mr. BAINES referred to the sound position of the Company, and said he thought that a higher dividend might be paid on the Ordinary shares.

The CHAIRMAN, in reply, stated that the Directors would be only too glad to pay an increased dividend when they felt that they would be justified in doing so. That time, however, was not yet.

The resolution was then unanimously passed.

On the motion of Mr. JOHN NEWTON, seconded by Mr. BAINES, a cordial vote of thanks was passed to the Chairman and Directors for their services.

The CHAIRMAN, in acknowledging the compliment, said it was extremely gratifying to his colleagues and himself to receive a vote of thanks from the shareholders at the instance of two gentlemen like Mr. Newton and Mr. Baines, who had formerly been among their principal critics. If Mr. Baines had all the information which the Directors were possessed of, he was sure that that gentleman would feel satisfied that the policy which the Directors were pursuing was not only the most prudent one, but also the best in the permanent interests of the Company generally.

The proceedings then terminated.

(A full report of this meeting will appear in our next issue.)

West African Telegraph Company (Limited).

The ninth ordinary general meeting of this Company was held yesterday (Thursday) at Winchester-house, Old Broad-street, under the presidency of Sir John Pender, G.C.M.G., M.P.

The SECRETARY (Mr. John Cambrook) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN then said: Gentlemen, before asking you to adopt the report and accounts, I will, as usual, make a few remarks on the accounts and the position of the Company generally. Our gross revenue for the year 1893 amounted to £61,847, as against £60,923 for the year 1892, or an increase of £924. There is an increase in Cape joint-purse traffic and also in certain local traffic; but, on the other hand, there is a decrease in the traffic with the French and British stations and with South America, so that the net increase in the message receipts is £644. Although the loss on exchange is still very heavy—namely, £7,751—it is £293 less than it was in 1892. The total working expenses for 1893 amounted to £18,829, as against £20,019, or a decrease of £1,190; the principal decreases being under the heading of general expenses in London £333 and in working expenses at stations, £819. The most rigid economy is practised, and it is satisfactory to note that those expenses over which the Directors have control show such a considerable reduction. Repairs to cables amounted to £31,234, as against £13,964 in 1892, or an increase of £17,270. Full details of the work done on account of repairs during the year will be found in abstract C of the report. As foreshadowed at the last general meeting, the cost of repairs during the last year has been exceptionally heavy; but, looking to the fact of our relations with the other companies, who are, with us, so much interested in the joint-purse traffic with the Cape, it was absolutely necessary that every endeavour should be made on our part to maintain the through communication. We have, therefore, at considerable cost, diverted the cable, as far as it was considered necessary, out of the region affected by the River Congo, and we can only hope that the cable will now be free from the frequent interruptions which have taken place in that district. In order to meet the deficit and to balance the revenue account we have, as stated in the report, applied the sum of £10,741 from the reserve fund, and we trust that the result of next year's working will prove more satisfactory. The Directors sympathise with the shareholders in their having again to go without a dividend, but they may rest assured that every consideration has been given to the matter, and the cause of the heavy expenditure has been beyond the control of the Directors. It is not a very pleasant report on this occasion that we have to submit. I never present any report or make any statement which results in no dividend without considerable pain. I may tell you that this Company has, so far, very much disappointed us. It has completed the link, it is true, in supplying Africa with telegraphic communication wherever it is brought from the interior; but, unfortunately, our cable in the first instance was not laid in proper water. I do not attach any blame to anyone for that, because we are only finding out from day to day and from time to time the difficulties of submarine telegraphy. If we get a good sound bottom we are sure that our cable will lie safely and work for a very long period of time, but if we get a bottom which is influenced by the current of such a great river as the Congo, we are sure to have disturbances; and in this case those disturbances occurred so frequently that we finally resolved to carry the cable out to sea about 140 miles. We are now, I hope, working more satisfactorily. We have another great difficulty to meet in the exchange. As I have just said, £7,700 has gone in that way, and in a small company that is an enormous loss. How or when that is to be remedied it is difficult to say. There is only one way of dealing with it, so far as we ourselves are concerned, and that would limit traffics—namely, by charging extra rates. We do not, however, find that that answers, so far as regards giving us very much more money, but we keep all these things in view; and my own impression is that if we are anything like fortunate in having our cable free from breakages, and, consequently, from repairs, we shall soon get into a sound state, and be able to meet our shareholders with a great deal more pleasure than we do on the present occasion. I can scarcely say more than that the most rigid economy is being exercised in every possible way, and I am hopeful that the money we have spent will enable us to work so efficiently that we shall soon be able to pay a dividend. With these remarks I beg to move—

"That the report and accounts for the year ending December 31, 1894, submitted to this meeting, be, and they are hereby, received and adopted."

Sir HENRY C. MANCE, C.I.E., M.Inst.C.E., seconded the motion.

The CHAIRMAN expressed his readiness to answer any question, but no shareholder rising to address the meeting, he put the motion in the usual way, and it was carried unanimously.

Sir H. C. MANCE then proposed the re-election of the retiring Directors, Sir John Pender and Mr. Thomas Fuller. He regretted that Mr. Fuller was absent on account of illness, but that gentleman was associated with companies with which their own undertaking was closely allied, and with which they had most advantageous working agreements, and he was a most useful and valuable member of the Board. With reference to Sir John Pender, nothing that he could say would add to the opinion of the shareholders regarding that gentleman's merits as Chairman of the Company. Only those who were closely associated with Sir John Pender could fully appreciate the great attention which he gave to the affairs of the Company. He was sure that no one felt more keenly than the Chairman did in having to meet the shareholders without a dividend, but he (the speaker) was perfectly certain that they would soon rejoin the ranks of dividend-paying companies under Sir John Pender.

Mr. ROBERT K. GRAY seconded the motion, which was unanimously adopted.

The CHAIRMAN: I am very much obliged to you for this further mark of your confidence. I can only say that if good wishes and close attention to the interests of the Company will bring about a dividend soon, you may depend upon it that it will come. This cable forms a very important link in a great system, and there is no link in the chain which ought not to have its fair proportion of remuneration; but when you see the sum of £31,000 paid for repairs on the one hand, and the heavy loss I have mentioned by exchange on the other hand, a very good traffic is required to meet such drawbacks. I might, however, have remarked upon one other point, which is that we are passing through extraordinary financial depression; but, as a cycle of bad times is followed generally by a cycle of good times, I hope that the good times will come, when we shall be able to meet you with a more favourable statement. I will only add that it will be the wish of my colleagues and of myself to bring that about as soon as possible.

On the motion of Mr. ALEXANDER HENDERSON, seconded by Mr. CUNLIFFE OWEN, the auditors, Messrs. Deloitte, Dever, Griffiths, and Co., were re-elected.

The CHAIRMAN: I think I have said before here, and I take the opportunity of repeating it from time to time, that with the way in which our accounts are audited they are practically controlled by the auditors—not controlled in the sense of alterations; but these gentlemen see that every item is dealt with in its proper place, and that no items are put into the accounts which ought not to appear, properly and honestly, where they are shown. They have long been associated with our telegraphic enterprise and understand it thoroughly well, and they do their work as they ought to. That concludes the business of the meeting.

On the motion of Mr. CUNLIFFE OWEN, seconded by Mr. J. T. EAST, a vote of thanks was passed to the Chairman and Directors for their able administration of the Company's affairs.

The CHAIRMAN: It is a great satisfaction to me, even at a meeting like this, to have such an expression of opinion on the part of the shareholders as to the manner in which we discharge our duties. We as much regret the absence of a dividend as any of you, but I hope that this will not last long.

The proceedings then terminated.

NEW COMPANIES, STATUTORY RETURNS, &c.

[In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1894, pages 274-300, *&c., &c.]*

AMERICAN AND PARISIAN MASSAGE COMPANY (LIMITED).—This Company has been registered with a capital of £10,000 in £5 shares, to enter into an agreement with F. Kennedy, and to provide premises for the carrying on of massage and medical electricity.

BELCHER'S PATENT SMOKE-PREVENTER COMPANY (LIMITED).—This Company has been registered with a capital of £1,000 in £1 shares, to acquire certain patents relating to improvements in the furnaces of steam boilers.

Digitized by Google

EGYPTIAN TRAMWAYS CONSTRUCTION COMPANY (LIMITED).—This Company has been registered with a capital of £6,000 in £1 shares, to acquire, develop, and deal with tramway concessions in Egypt and elsewhere.

STANDARD WIRE COMPANY (LIMITED).—This Company was registered on July 4th, with a capital of £50,000, in £10 shares, to purchase the business of manufacturing wire, carried on by the Standard Wire Company, at Sowerby Bridge, Yorks.

W. AND F. WILLS (LIMITED).—This Company was registered on July 3rd, with a capital of £10,000, in £5 shares, to acquire the business of mechanical and consulting engineers, millwrights, and iron and brass founders, carried on under the style of W. and F. Wills.

RIVER PLATE ELECTRICITY COMPANY (LIMITED).—The annual return of this Company made up to May 31, 1894, was recently filed. The nominal capital is £500,000 divided into 49,900 Ordinary shares of £10 each, and 1,000 Founders' shares of £1 each, 13,557 Ordinary, and 892 Founders' shares, have been taken up, and 2,400 Ordinary have been issued as fully paid. Upon the remaining 11,157 Ordinary and 892 Founders' shares, the full amounts have been called, resulting in the payment of £110,892, and eaving £1,570 as yet unpaid.

RONALD A. SCOTT (LIMITED).—An agreement, dated June 20, 1894, with Mr. Ronald A. Scott, states that as part of the purchase consideration 1,000 £1 fully-paid shares, Nos. 1 to 1,000, have been allotted to the vendor.

SAXBY AND FARMER (LIMITED).—The first annual return of this Company, made up to June 29th, has been filed. Out of a nominal capital of £25,000, in £10 shares, 2,021 have been taken up, and of these 1,800 were issued as fully paid in part payment of the purchase consideration. Upon the remaining 221 shares the full amounts have been called and paid.

SYNDICATE OF ELECTRICAL ENGINEERS (LIMITED).—The annual return of this Company, made up to March 27th, has just been filed. Out of a nominal capital of £10,000, divided into 1,900 Ordinary and 100 Founders' shares of £5 each, 1,007 Ordinary and all the Founders' shares have been taken up, the latter being issued as fully paid. Upon the Ordinary shares calls amounting to £4 per share have been made, resulting in the payment of £4,003. 10s., and leaving £24. 10s. in arrears.

CITY NOTES.

CAPE TOWN AND SUBURBAN ELECTRIC LIGHTING SYNDICATE (LIMITED).—It is stated that a dividend of 5 per cent. has been declared by the Directors of this Company.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended July 8th were £879, as against £1,069 in the corresponding period of 1893 (which included the Royal Wedding-day, July 6th), being a decrease of £190. The total receipts for the half-year amount to £24,515, as against £23,679 for the corresponding period of 1893, an increase of £836.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The revenue return of this Company for the quarter ended June 30th is as follows:—Sale of current for public lighting, £3,162, against £2,839 in the corresponding period of 1893; private lighting, &c., £7,153, against £3,074—total, £10,315, against £5,913. The equivalent of 8-c.p. lamps connected in June, 1894, was 99,140, against 45,562 in June, 1893.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).—The Directors of this Company have resolved to recommend a final dividend of 2s. per share, free of income tax, to be paid on and after the 25th inst., and making, with the interim dividends already paid, 2⅝ per cent. for the year ended June 30th. £6,000 is placed to reserve, and a balance of £1,031 17s. 2d. carried forward. The transfer books of the Company will be closed from the 10th to the 24th inst. inclusive.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The interest on this Company's Four per Cent. Mortgage Debenture Stock for the half-year ending July 31st inst. will be paid by warrant on August 1st next. The Stock Register will be closed from the 27th to the 31st inst., both days inclusive.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—The eleventh ordinary general meeting of the shareholders of this Company will be held at the Cannon-street Hotel, E.C., on Thursday, July 26th, at 11 a.m., when the report and accounts of the Directors will be discussed.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company for June, 1894, amount to £24,000, and from January 1st to June 30, 1894, £129,800. In the corresponding months of 1892 and 1893 the amounts were £128,800 and £134,800 respectively.

LONDON TRAMWAYS COMPANY (LIMITED).—A meeting of the shareholders in this Company was held on Tuesday last, and Mr. D. P. Sellar, who presided, dealt at length with the result of the lawsuit between the London Street Tramways Company and the London County Council before the Court of Appeal. He said it was much to be regretted that the plaintiffs were the London Street Tramways, which Company came into existence in 1870, and was therefore not able to appeal to the Act of 1869 to elucidate the meaning of the purchase clause of the Act of 1870. Their own Company and the North Metropolitan Company were in a different position, both being established by an Act of Parliament passed in 1869. Although the purchase clause in their Acts was altered in conformity with the General Tramway Act of 1870, they could still appeal to their Act of 1869 to prove the meaning of the Act of 1870. By the purchase clause of the Act the Company was to get paid "full value" for its tramways, &c., and to have not only payment for goodwill of the business, but also for "prospective value"—that was to say, for future profits; a payment was also to be made to compensate the Company for compulsory sale. In the 1870 Act this clause was altered to "then value," and after "value" came in the excluding clause, "exclusive of any allowance for past or future profits of the undertaking." The fact was, the County Council desired to acquire the most profitable section of the dividend-paying tramway companies, valuing them at structural cost, less depreciation, which was simply a game of "Heads I win, tails you lose."

MANITOBA ELECTRIC AND GAS LIGHT COMPANY.—The interest due on July 1st on the debentures of this Company have not been paid. This is stated to be owing to legal difficulties, which will shortly be removed.

NATIONAL TELEPHONE COMPANY (LIMITED).—The Directors of this Company have resolved, subject to final audit, to recommend at the forthcoming general meeting the following dividends, less income-tax, for the six months ended June 30th last:—At the rate of 6 per cent. per annum on the amount paid up on the First and Second Preference shares; at the rate of 5 per cent. per annum on the amount paid up on the Third Preference shares; at the rate of 5 per cent. per annum on the amount paid up on the Ordinary shares, making, with the interim dividend already paid, 5 per cent. per annum for the twelve months ended June 30th, and leaving a balance of about £67,000. The transfer books of the Company will be closed from July 13th to 26th, inclusive, and dividend warrants will be posted on the latter date.

NOTTING HILL ELECTRIC LIGHTING COMPANY (LIMITED).—A meeting of the shareholders of this Company, called for the purpose of considering some slight alterations to the Articles of Association of the Company, was held on Tuesday last at the offices, Bulmer-place, High-street, W. This Company has declared a half-yearly dividend on its Preference shares at the rate of 6 per cent. per annum.

PRINTING TELEGRAPH AND CONSTRUCTION COMPANY (LIMITED).—The action brought against this Company by Mr. Elvey has been settled, it being agreed that an order should be taken striking Mr. Elvey's name out of the list of shareholders.

SOCIETE FRANCAISE DES TELEGRAPHES SOUSMARINS.—The annual meeting of the shareholders of this Company was held in Paris on the 28th ult., when the accounts were approved, and M. Rouget, the retiring Director, was re-elected. The meeting also ratified the election by the Board as Directors of Messrs. F. Sollier and Le Raguet de Brancion.

ST. JAMES AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED).—The current sold by this Company during the quarter ended June 24th, last amounted to £7,380, against £5,848 for the corresponding period of 1893.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have ordered the £30,000 Four and a-Half per Cent. Debentures, Nos. 1 to 600, of the Direct Spanish Telegraph Company (Limited) to be quoted in the Official List.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED)—This Company have declared an interim dividend of 12s. per share.

THE TELEGRAPH IN NORTH BORNEO.—Speaking at the meeting on Tuesday of the British North Borneo Company, Mr. R. B. Martin, M.P., who presided, said that the cable had been successfully laid between Singapore and Labuan by the Eastern Extension Telegraph Company, and arrangements had been made with that Company, in condition of their connecting Labuan with the Company's territory, to continue a land-line across to Sandakar. He took that opportunity of complimenting the Eastern Extension Company on the prompt and business-like manner in which this work was carried out; and must also mention that in all their dealings with that Company in this matter they had been met in the most liberal spirit. From all information which they could gather, communication could be established for a moderate sum, which had been voted for the purpose. It was impossible to tell the exact sum, but it would not be more, probably, than £7,000 or £8,000 at the outside. Although this undertaking might not be immediately reproductive, the importance of it must be apparent to all; for instance, it takes three months to get a reply to a letter from Borneo, and formerly it took a month to get a reply by wire. Recently we have been in communication with our Governor, receiving a reply to a message sent off at 5 p.m. at 11 a.m. on the following morning. The track through the country may discover tobacco land or minerals which will recoup the outlay. It will bring us more *en rapport* with the natives of the interior, and will be a great boon to the traders, planters, and others interested in the development of the country. We know that as far as Labuan is concerned the line will be constantly in use, and, being so near it, we hope we shall find our merchants able to use it to a considerable degree. I look for very great advantage, both direct and indirect, from the introduction of the telegraph into our country. The energy displayed by the British North Borneo Company's officers entrusted with the work of helping to connect Labuan with our territory by cable was especially noticed and reported upon by the telegraph company's officials.

WATERLOO AND CITY RAILWAY COMPANY.—A general meeting of the shareholders of this Company is to be held at Waterloo Station, S.W., on Thursday, August 9th, at 2:30 p.m.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended July 6th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £2,378.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the two weeks ending June 30th were £2,279, as compared with £2,295 for the corresponding period of last year.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 844.—Vol. XXXIII. FRIDAY, JULY 20, 1894. PRICE SIXPENCE. Annual Subscription (U.K.), 19/6

NOTES.

The Committee appointed to report on the distribution of a grant of £15,000 for University Colleges in Great Britain have presented their report, which has just been issued as a Parliamentary Paper. With the exception of a grant being made to Bedford College, London, and the reduction of the original (1891) grant to Nottingham, the list stands in practically the same state as when first drawn up three years ago. It is remarkable that the whole of this particular grant falls to English institutions. Owens College, Manchester, heads the list with £1,800 per annum; the next being the London University College, which is to receive £1,700. Seven provincial colleges follow, each receiving £1,200 or more; and Bedford College, London, ends the regular list with £700. These make a total of £13,300, and the balance is offered to King's College, London, "on condition of its removing within the present year the denominational tests from all its teachers, other than theological." The recommendation made by the Committee that, except in cases of inefficiency, the grants should be continued without readjustment for a period of five years, has been accepted by the Treasury. We gather from a letter written by Dean Wace to *The Times* that the constitution of King's College, London, is such as to preclude the removal of the "religious test" from its staff of teachers, and that the abandonment of the Parliamentary grant on the conditions imposed is inevitable in this institution.

The experienced medical man alone knows the thousand dangers of every breath, every footstep, and, indeed, every act of man's life; and it is well that nervous laymen should remain in ignorance of the calamities which might befall them at any moment. A correspondent points out this week that Hertzian waves might set up or start an arc between neighbouring conductors during a thunderstorm, and he treats the matter as a serious danger. Not long ago a solemn warning was given about the risk of embroidering table-cloths with metallic thread, since it was alleged that a thunderstorm had actually ignited or singed such a fabric, though the house was not struck. The case seems to have been unique; but, so far as we are aware, no instance of the arcing between conductors during a thunderstorm has occurred in ordinary house wiring. Hundreds of armatures of dynamos and motors have been burned out through lightning flashes, but that is another problem. Attention was called some time ago to the sparking of gas pipes during a thunderstorm; but the fact remains that not a single fire has been recorded, in this country at all events, during a thunderstorm that could be attributed to a secondary effect in electric lighting conductors. That such an accident is conceivable is not to be denied, and in the meantime we should like to see some simple and unpatented substitute for wood casing.

Our American contemporary, the *Electrical World*, recently discussed in an editorial note the question of the value of sine curves for the electromotive force of alternators. We have ourselves already remarked on this question, and have expressed our opinion, which we know to be shared by alternator experts in this country, that the elaborate attempts which are being made by some of the American alternator builders to give this property to their machines are utterly useless, and a complete waste of time and energy. Our esteemed contemporary, however, thinks differently, and bases its conclusions on the deductions of Kennelly and some experiments by Dr. Duncan on two-phase motors. It is, therefore, apparently supported by both theory and practice; yet, when we examine the matter a little more closely, we are by no means inclined to agree that our contemporary has sufficient grounds for its conclusions. In the first place, theoretical considerations, especially of the intricate phenomena of alternate current machinery, are apt to ignore those influences which, though difficult to put into exact mathematical form, are just the things which determine the truth or fallacy of the conclusions. Again and again this has happened, and it has been shown that mathematical inference, unsupported by experimental evidence or based on insufficient data, cannot be relied on.

It may, perhaps, be argued that the results of Dr. Duncan's researches afford this necessary experimental evidence. Let us see what these researches amount to. Dr. Duncan commences by observing that "the mathematical treatment is difficult, unless many essential phenomena are omitted." He then describes some experiments on a two-phase 2-h.p. Tesla motor. This motor was run from a 25-h.p. two-phase generator, which was believed to give practically a true sine curve of electromotive force. The results obtained were not

Digitized by Google

compared with those which might have been obtained from any other alternator; they therefore stand alone. Moreover, the motor was not even run up to its full capacity, nor was it supplied with its rated electromotive force; so that it was "not, of course, particularly efficient." In all of which, we may ask, is there anything to show that the motor was more efficient than it would have been in any other case? Nor are the practical rules for design, which follow from these deductions, any more comforting to the builder of alternate current machinery. "To satisfy the condition in the armature would require an infinite number of armature windings, but it can be practically satisfied in the higher machines with a reasonable number of windings. It must not be understood that it is specially easy to accomplish this." So much for the true sine armature; as to the field windings, "projecting pole pieces should certainly be avoided." We should not be surprised to hear that the sine curve should be carefully avoided, and that the "best" curve is of a very different shape.

The abstract of the Paper by M. Charles Henry, which will be found in another column, should prove of interest to electricians. The sensitiveness of the eye is subject to great alterations caused by the changes in the diameter of the part of the pupil exposed. These changes are due to the amount and character of the illumination falling upon the eye. The study of what causes these changes is as important for electric lighting purposes as consideration of the efficiency of dynamos. A few per cent. at most can be gained by exchanging a dynamo for one of a better make; whereas, for the same amount of lighting power illuminating two areas, if the distribution is bad in one case and good in the other, it may be that in the latter instance the eye is far more sensitive than in the former, and, in consequence, much less light would produce the same illuminating power. An accurate method of measuring the sensitiveness of the eye when subjected to various kinds of light is, therefore, a great desideratum. Unfortunately, although M. Henry describes a large number of methods, some of them very fairly sensitive ones, for measuring the diameter of the eye, none of these are such that the eye under test can be exposed to the illumination whose character it may be desirable to investigate. In most of these methods the eye is shut off from the light while being experimented upon. A simple modification of Robert-Houdin's method might, however, be adopted, in which this defect would be absent. If two bright beads are used instead of two little holes, the instrument would work just as easily, and the eye would be exposed to the light during the whole time. We have made a few rough trials with such an arrangement, and think that it might be usefully employed in conjunction with a photometer for street lighting. Low lamp standards and clear glass globes would give a high mean illumination as measured by a photometer; but the effect would not only be very unpleasant, on account of the glare, but the pupil would become so contracted that the eye would receive less light in the neighbourhood of a lamp than that which would be indicated by ordinary photometric methods.

The Corean Crisis.—According to a correspondent of *The Times* the Japanese Minister requires the unconditional acceptance, by Corea, of 25 demands, one of which is the concession for a telegraph line.

Cable Interruptions and Repairs:—

	Date of Interruption.	Date of Repair.
Bissao-Bolama	Nov. 24, 1893	July 14, 1894.
Sierra Leone-Accra	July 2, 1894	—

Correspondence.—We have received a letter from Dr. A. Koepsel on the subject of the article by him in *The Electrician*, July 6, 1894. We hope to publish a translation of this letter next week, as it reached us too late for the current issue.

University College, Bristol.—The session 1894-95 for electrical engineering, also for the chemical department, begins on October 4th. Particulars of the course of lectures arranged and other information will be found in our advertisement columns.

University College of North Wales.—Prof. A. Gray will begin in October next a systematic course of instruction in electrical measurements and practical electricity at the above college. The laboratory is now fully equipped with machinery and instruments. Copies of the calendar prospectus, &c., can be obtained of Mr. J. E. Lloyd, M.A., at the College, Bangor.

Obituary.—We regret to announce the death, at the age of 57 years, of M. Paul Lemonnier, formerly a member of the well-known firm of Sautter and Lemonnier, of Paris. M. Lemonnier was very largely interested in the introduction of the Gramme armature and dynamo, and took an active interest in their manufacture during the early years of electric lighting. The death has also recently occurred of M. E. Julien, whose enterprise in connection with secondary battery work is well known to our readers.

A Master-Patent.—One of our American contemporaries announces that a Mr. Van Choate, of Boston, has issued a notice to everybody in general, and to some of the electrical companies in particular, that he controls by patent all multipolar motors and generators, as well as every electric street car now in use. Mr. Choate, our contemporary thinks, is too modest to live in Boston.

Telephonic Communication in Spain.—We learn from Spain that, under the auspices of the same English capitalist who formed the Sociedad de Telefonos de Barcelona, a company has just been formed with a capital of £120,000, to be known as the Compañia Peninsular de Telefonos. The object of the Company is to establish telephone lines in the Peninsula and to acquire the Bilbao-Santander line.

Shoddy Work and Underbidding.—The *Electrical Review* of New York complains that an analysis of some tenders recently offered for the construction of an electric plant in the United States show that some of the bidders actually offered to construct, equip, and place the entire plant in operation for a less sum than the material alone could be purchased for in open market. We are not entirely unacquainted with this sort of thing on this side of the Atlantic.

Prof. von Helmholtz.—We regret to announce that Prof. von Helmholtz has, during the past week, had a paralytic stroke; but the gratifying intelligence has since reached us, by telegram, that he is now better. He had rather a restless night on Sunday, but on the following morning was able slightly to move the limbs of his paralysed left side. The latest information leads us to entertain the hope that the distinguished patient will soon recover from his attack.

Electrolysis of Water-Pipes.—The electrolysis of water-pipes has, it is stated, become a serious matter in San Francisco. A 30in. pipe belonging to the Spring Valley Water Company has lately been repaired so often that a number of measurements have been made of the electrical conditions about it. It is stated that at one point the difference in potential between the pipe and the neighbouring rails of an electric road was 16 volts, and that the current amounted to 116 amperes.

Telephonic Communication in Austria and Hungary.—The Chamber of Commerce of the now flourishing port of Fiume has petitioned the Hungarian Minister of Commerce, asking that a direct telephone line shall be established between Fiume and

Digitized by Google

Budapest. The Austrian telephone system is about to be greatly extended. A trunk line is to be run from Salzburg to Linz. Lines are also to be established from Prague to Aussig, and from Brünn to Olmütz.

The Giffard Prize.—It is stated that the Commission of French Civil Engineers appointed to decide as to the competitive subject for the Giffard prize of 1896 have resolved upon the following:—The transmission of power by electricity in various applications, machine tools, railways, tramways, bridges, ships, docks, &c. Those competing must commence the essay by a summary of the present condition of the subject, and give the details of some scheme which has been executed, or the draft of a suggested scheme.

Electrical Utilisation of Water Power in Austria.—Messrs. Ganz and Co., of Buda-Pesth, are at present engaged in establishing an electrical power transmission plant near Sebenico, in Dalmatia, to utilise the power of the well-known Kerka Falls. It is stated that no less than 1,600 H.P. is available, although the present plant will only have a capacity of 300 H.P. The electrical energy thus generated is to be transmitted to Sebenico, at a distance of about 7 miles, where it is to be utilised for lighting and power purposes. The town itself is to be lighted by 3,000 incandescent lamps.

Electric Traction in Japan.—The question of electric traction appears to be disturbing the peace of mind of the Japanese, several schemes having recently been brought forward for the establishment of electric tramways, none of which, however, have as yet been put into practice. The latest proposal is for an electric railway, 20 miles long, from Yorü in Hanzawagun, *viâ* Kumagaye and Oski to Bessho-gasti in Kitá-Sartania-gun. It is intended to utilise certain available water-power in the generation of the necessary electrical energy. The estimated cost of the line is £60,000.

Telephonic Communication in Spain.—During the last few years the adoption of the telephone has made rapid progress in Spain. Already no less than thirty-seven different towns throughout the country are provided with exchanges, and new lines are being established in all directions. Among the latter we may mention that an exchange is about to be established at Mataro, a busy seaport town in Catalonia, about sixteen miles from Barcelona. At the same time a line will be run to the latter town, which will put Mataro in direct telephonic communication not only with Barcelona but also with Tarrasa, Sabadell and Manresa.

Expensive Telephoning.—As our readers are aware, a telephone trunk line has just been opened between Scarborough and Leeds. Owing to local opposition the capital expenditure has been very large, so that it has been thought necessary to impose an unusually high tariff on subscribers and the public who may use the line. Subscribers will have to pay ninepence for every three minutes conversation, while non-subscribers will be charged for the same facility eighteenpence—or at the rate of thirty shillings an hour. A three minutes conversation to London will cost the non-subscriber about nine shillings, and the subscriber half that amount.

Electric Traction at Havana.—The tramways in Havana and the suburbs, which are owned by a company called the Ferro Carril Urbano, comprise a steam tramway from Havana to Vedado, a suburb three miles distant on the sea coast, and three lines of horse trams to Castillo del Principe, Cerro, and Jesus del Monte. The fare is 2½d. or 5d., according to distance. According to the British Consul-General arrangements have been made by an English company for laying down an electric tramway. The projected line is twenty miles long, and its principal object is to connect the main thoroughfares and wharves with the existing tram lines.

Personal.—Mr. Arthur A. Voysey has been appointed to fill the post of electrical inspector to the City Commission of Sewers. The duties comprise the inspection of the public street lighting, and the supervision and testing of meters, on behalf of the City. Mr. Voysey was formerly a student at the Hanover-square School, and on the staffs of Messrs. Siemens and Co. and Messrs. Callender and Co. The salary is £250 per annum. 88 applications for the post were received. Mr. Voysey received 32 votes out of 54. £10 was granted to each of the two candidates left in the final voting—Messrs. Gerhardi, jun., and Carver.——Dr. C. Dieterici, Professor of Philosophy at the University of Breslau, has been offered, and has accepted, the Professorship of Physics at the Technische Hochschule at Hanover.——Prof. F. Kohlrausch, of the Strasburg University, has been appointed to succeed the late Prof Kundt in the Chair of Physics at the Berlin University.

House of Commons Accommodation.—The Select Committee of the House of Commons, which is engaged in considering the accommodation of the House, sat again last Wednesday, when the following among other suggestions was made, with a view to carrying out the desired improvements. It is proposed to construct a large room immediately adjoining the gallery, fitted with separate boxes for telegraphic and telephonic instruments, and seats for the chief messengers. This room, known as the "Instrument Room," should be in telephonic communication with the reporters' writing-room in the House of Lords, and in tube communication with the Star Chamber (junior messengers' room), which should also be enlarged by the partial absorption of the existing passage.

Signal Wires in the Cable Conduit.—The Broadway and Seventh Avenue Railway, of New York City, says the *Street Railway Gazette* of New York, has won a decided victory in its fight with the Empire City Subway Company (Limited) in regard to its right to use the conduit running along its line of road from the Battery to Fifty-first street, for wires and electrical conductors in order to signal to any portion of the road in case of accident or for other cause. Judge Ingraham, in the Supreme Court, gave a decision holding that the subway company has no right to maintain action to enjoin the railroad company from maintaining electrical conductors in its conduit for the necessary and proper operation of its road. Judge Ingraham holds that the licence of the Subway Company is not an exclusive right to maintain subways in New York City.

Electric Lighting in Spain.—Electric lighting is about to be introduced into the Conservatorio de Musicá, in Madrid, tenders for the work having just been invited. A company is in course of formation to establish a central station at Manresa, a busy and thriving town in Catalonia, near Barcelona. A central station has just been completed and put in operation on the banks of the Nervion, opposite Bilbao, and is intended to supply current for lighting purposes to the districts of Baracaldo, Sestao, Portugalete, Santurce, and other places. The plant which has been put down by Messrs. Schuckert and Co., of Nuremberg, Germany, comprises two steam engines and dynamos having an output of 100 kilowatts. Work has also just been commenced on the establishment of a central electric lighting station at Seode, Urgel, for public and private lighting purposes. The plant is being supplied by a German firm, the Deutsche Electricitätswerke of Aix-la-Chapelle.

Telephones in the City.—At a meeting of the City Commission of Sewers, held at Guildhall on Tuesday, Mr. Gordon moved to rescind a resolution of the Commission a year ago consenting to the use for telephonic purposes of certain tubes laid by the City of London Electric Lighting Company on a guarantee being given that telephones with double wires and all the latest improvements would be supplied to the citizens at a cost not exceeding £8 per annum; and to substitute for it an acceptance of the Company's offer to pay 10 per cent. of any annual rental so long as such might be received for the use of any tubes for telephonic purposes up to £10,000, and 20 per cent. on any rental in excess of £10,000, the *minimum* amount to be received by the Commissioners being £1,000 a year. The motion to rescind was adopted by 25 votes to 19, but as this did not constitute the necessary two-thirds majority to rescind the previous resolution the proposal fell to the ground.

Meteorology in France.—The Central Meteorological Office of France has just published its *Annales* for the year 1892, consisting of three large quarto volumes. Vol. I. contains a number of memoirs, among which there is one by M. Fron, on thunderstorms in France during the year. These summaries have been continued for thirty years, and furnish useful data

Digitized by Google

for determining the laws which underlie the formation and propagation of those phenomena. M. Moureaux discusses the observations on terrestrial magnetism at the Parc Saint Maur, and gives curves for the self-recording instruments of the most remarkable disturbances, which were considerable during that year. He also contributes a Paper on the magnetic conditions at 100 stations; there are altogether 428 such stations in France; those not yet dealt with will be discussed in subsequent years. Finally, M. Durand-Gréville gives a detailed investigation of the connection between squalls and thunderstorms, and has determined some of the phenomena which regularly accompany the formation and propagation of the latter. Vols. II. and III. deal respectively with the ordinary observations and with rainfall values at a large number of stations.

Proposed Underground Electric Railway for Vienna.—The Anglo-Austrian Bank and Messrs. Siemens and Halske have submitted to the Austrian Board of Trade detailed plans for an underground electric railway in Vienna. The railway is to be of narrow gauge, with double track, and is to commence at the Danube Canal, pass under the central city to where it touches the western suburbs, continue under the Maria-Hilfstrasse to the western terminus, and thence to the outskirts of the city to Schönbrunn and Penzing. The railway would be laid deep enough so as not to interfere with the foundations of houses. The journey between the two termini is to be accomplished within eighteen minutes. A single carriage, to be started at short intervals, is intended to convey 40 passengers in ordinary times, while in the morning and evening, and on Sundays and holidays, cars are to be added. Should leave be given for the construction of the work, building operations are to commence at seven different points at once, so that it would be possible to complete the railway in a year from the date of the concession. As there are no means of rapid communication in the central part of the city, the Viennese look with great favour upon the undertaking.

Magnetic Rotatory Dispersion of Oxygen.—In No. 7 of the pamphlets which the Physical Laboratory of the University of Leyden is issuing under the direction of Prof. Kamerlingh Onnes, says *Nature*, there is an interesting Paper by Dr. L. H. Siertsema on the magnetic rotatory dispersion of oxygen. In most substances the magnetic rotatory dispersion approximately, at any rate, follows the law that governs natural rotation—viz., that the rotation varies inversely as the square of the wave-length. In strongly magnetic bodies, such as solutions of iron salts, the dispersion is much greater, according to Becquerel the rotation being proportional to the fourth power of the wave-length. Oxygen seems to be an exception, for while Becquerel thought he obtained a small dispersion, more recently Kundt and Röntgen obtained no dispersion. The arrangement of the apparatus employed by the author resembles that used by Kundt and Röntgen. The gas under high pressure is enclosed with a polariser and analyser in a long tube, and the rotation is obtained by fixing one end of the tube and turning the other, so that torsion is given to the tube. The tube lies in a long magnetising coil containing 3,600 turns, and through which a current of 70 amperes is passed. Some preliminary experiments made with commercial oxygen at a pressure of about 100 atmospheres, have shown that, contrary to the result given by Becquerel, Verdet's constant for oxygen decreases regularly with increasing wave-lengths, and that for violet it is twice as large as for red.

Submarine Telegraph Commemoration.—The banquet and reception to be held at the Imperial Institute to-day, in commemoration of the 25th anniversary of the establishment of submarine telegraphy to the Far East, will be a great feature of the season, and will be on a larger scale than anything of the kind which has taken place. There will be about 450 guests at dinner, and over 4,000 at the reception. Amongst those who will be present at the latter are their Royal Highnesses the Prince of Wales, the Duke of Cambridge, the Princess Louise, the Duke of Fife, the Marquis of Lorne, their Highnesses the Prince and Princess Edward of Saxe-Weimar, Prince Hermann of Saxe-Weimar, the Maharajah of Kuch Behar, the Turkish Ambassador, the Danish, Portuguese, and Servian Ministers, the Right Hon. Sir W. V. Harcourt, the Marquis of Salisbury, the Speaker, and many members of both Houses of Parliament, as well as distinguished representatives of the Navy, the Army, the Diplomatic Service, the Colonies, &c., &c. Amongst the principal guests at the dinner, who will also attend the reception, are the Italian and United States Ambassadors, the Netherlands, Persian, and Japanese Ministers, Secretaries to Embassies and Legations, the Lord Chancellor, the Lord Mayor of London, and the Mayors of several cities and towns. Elaborate arrangements have been made to provide against crushing or confusion, and a staff of stewards appointed to supervise the arrangements and promote the comfort and convenience of those invited. General directions to the reception guests are issued in circular form, which contains a list of special train arrangements. Twenty-five years ago a reception, at which the Prince of Wales was present, was held at Sir John Pender's house in Arlington-street to celebrate the opening of submarine telegraph communication to India; and it must be a great satisfaction to all those connected with the service to contemplate the enormous extension of the system during the last quarter of a century. The speeches at the banquet will be reported in our next issue.

Electric Traction for Canals.—According to a correspondent of the *Engineer*, the authorities of the New York State canals have taken an important step in granting the Cataract General Electric Company a fifty-year permit to put in some kind of an electric plant along the lines of the State canals, by which boats can be operated with electricity. The Company shall not charge for use of such power by the canal boatmen at a rate exceeding 20 dollars per electrical horse-power for each season of navigation; but that is the maximum charge that can be made, and the rate will undoubtedly be much lower. Even at 20 dollars a horse-power it is claimed that an owner would be saved 50 per cent. a season on the operation of his boat in comparison with the present cost of canal boat propulsion. The operations of the Company are not in any way to interfere with boats navigating the canal by steam or horse-power. The Company made several experiments on the canals last autumn, as previously noted, and the matter will now be pushed forward to a successful solution of the problem. The electrical power will be obtained from the Niagara Falls, and transmitted by wires erected along the line of the Erie Canal. The permit authorises the Company to enter upon all canal lands of the State for the purpose of constructing either on or over or under either canal bank a system for propelling canal boats by electricity, without interfering with the present method of operation. The rates for towage shall be subject to modification and review by the State Superintendent of Public Works, but such rate shall not exceed 20 dollars per electrical horse-power for any season of navigation. An important provision is that the Company may, so long as the wants of the canal are supplied, employ its electric plant along the line of the canal in furnishing electric light, heat, and power for distribution to any point or points beyond the line of the canal, and thus may furnish electricity for lighting and power purposes in all of the cities and villages along the canal. The Company is to furnish the State, free of charge, sufficient power to operate motors to open all gateways leading to and from locks, and also electric lights sufficient to properly illuminate such locks at night. The Company must have its plant for operating boats by electricity in operation on the Erie Canal between Buffalo and Albany within three years from date, or else the privileges accorded by the permit shall be forfeited. In case the Company shall construct along the canals an electrical plant for use, known as the trolley or overhead-wire system, it shall be the privilege of the State to condemn and purchase such property at a price equal to the actual original cost to the original constructor, with the 10 per cent. added thereto. Another electric traction project is that of the Erie Electric Towing and Power Company, which will construct and put into operation as soon as possible half-a-dozen tugboats, operated by electricity, either on the storage or trolley system, with a view of showing the adaptability of electricity to canal navigation. These tugboats will also tow for a moderate consideration any horseboats, the captains of which desire to avail themselves of such method of navigation.

ELECTRIC MOTIVE POWER.*

BY ALBION T. SNELL.

(*Continued from page 266.*)

Underground Cables, Junction Boxes, Switches and Cut-outs.

Each "district" is usually supplied from an independent pair of conductors coupled at the pit bottom to an omnibus bar or to a separate pair of shaft cables.

The conductors are, therefore, of small size, not often exceeding 19 strands of No. 16 S.W.G.

They are carried on the "sides" or "roofs," being supported by wooden cleats or earthenware insulators or buried in the "floor." The choice of the three methods will be determined by the peculiarities of the "level" in which they are run. The class of insulation will depend both upon the method of erection and the difficulties to be dealt with.

In dry roads, well supplied with timber props and cross bearers, a light vulcanised rubber cable carried in wooden cleats or on insulators will prove to be cheap and efficient. An occasional fall of roof or sides will not as a rule cut the conductor if a little slack be allowed between the supports; and "creeping" of the floor will not affect it. Indeed, in the majority of cases where long lengths of small conductors, about 7/16 S.W.G., have to be carried to the "faces," this is the only practicable method from simple considerations of cost.

Wood casing is out of the question for "road-work" except for the lighting circuit near the pit bottom. Not only from cost, but from the instability of most of the "roads."

In main engine planes which have no "weight" upon them, a permanent job may be made of the erection; and it will generally pay to bury the cables beside the metals and to loosely cover them. But a rough wooden trench with a covering board should be laid to receive the cables, unless they are armoured, for otherwise an unlucky blow from a pick might such cause a breakdown. If heavily armoured concentric cables, as shown in Fig. 102, p. 264, are used, it is sufficient to bury them about 6in. to 12in. below the surface of the road, well to one side, where they will be free from disturbance during repairs to the metals and roads. If conductors are carried along "travelling" roads, it is specially necessary to secure them from damage at the hands of the miners, who are sometimes inclined to get "lightning" from them by means of their picks. If the road be dry and in a fairly settled condition cables may be laid in fine coal dust, covered by rough boards 1in. thick, and then protected by a layer of coal dust of about 6in. deep. This forms a very safe and cheap bed for hemp-braided vulcanised rubber cables, or lead-covered cables served or braided with hemp. It is specially serviceable in travelling roads or where the conductors are laid for a temporary purpose.

Whatever the class of cable or the method of laying it, however, the conductor should not be in continuous lengths of more than about 500 yards, in order that a fault may be readily localised. At the junctions of sections cast-iron boxes (*see* Fig. 105) should be placed with screw terminals on porcelain bases, through which the necessary connections can be quickly made or unmade. On no account should cut-outs be placed at these points unless special provision be made to enclose them in flametight boxes. They should be confined as far as possible to the generating station and pit bottom.

At the far ends of the levels where the distributing mains are joined to the feeders, it is good practice to place cast-iron junction boxes in the "gates," so that any or all of the distributors may be coupled up according to requirements. It is imperative if cut-outs be used here, as is sometimes necessary, that they be placed in flametight boxes, for this position is close to the faces, from which gas may be given off at any time.

The "distributors" are necessarily of a temporary character and will be shifted as the work progresses. They must therefore be light and flexible. If possible they may be carried upon the props, and in the absence of timber may be laid beside the roads, unless they are hung on rough iron spikes driven into the rock. In any case they will often be subjected to rough usage. For attachment to movable machines, such as coal cutters and rock drills, it is usual to provide concentric or else twin cables, insulated with vulcanised rubber and braided with steel wires. Either of these can be made sufficiently flexible, and are also strong enough to stand being hauled across rough shale and coal.

If a distributor feed a dip pump, it should be erected in a semi-permanent manner; since such pumps are liable to be drowned-out, and the plant may have to be withdrawn several hundred feet or yards at short notice. In such cases the conductors should be brought back with the motor and not cut. They should be coiled and hung up at the pumping station, being uncoiled again as the water recedes. The best insulation for this work is vulcanised rubber well braided with hemp and ozokerited over all.

For a polyphase current system it is necessary to run three or four conductors in place of the two required for a continuous current or single phase alternate system. For permanent work, three conductors may be built into a concentric cable, which may be lead-covered and armoured, but with a four wire system two concentric cables of two conductors each are preferable. The method of erection is in no respect different to that adopted with continuous current working. The three wires are carried practically as readily as two.

The use of switches and fuses below ground in places likely to contain explosive gas requires careful regulation, and is likely to become the subject of special legislation in the future. The author states emphatically that in his opinion no switch, cut-out, junction box, or resistance frame that is not absolutely flame and dust-tight should be allowed in a coal mine where naked lights are prohibited. It is madness to forbid the use of a naked light and yet to allow the types of switches and cut-outs sometimes found in pits.

To ensure absolute freedom from firing gas with a continuous current motor is perhaps impossible, but no such difficulty should be found with small stationary devices such as switches, cut-outs, and junction boxes. It is merely a matter of expense, and should be insisted upon in all permanent plants.

Uninsulated Returns—Safety Cables.

It has been the custom at some pits to use old iron ropes as returns. These are simply laid along the roads or hung up by hooks to the side props. The practice, however, is not to be recommended in pits where there is any chance of gas, and in a large plant with a pressure of 500 volts would in any case be impossible. The author coupled a return in this manner at Andrew's House Pit, Durham, in 1887, the arrangement being adopted simply from considerations of first cost. The pressure at the dynamo terminals averaged 225 volts, and the power in this part of the circuit never exceeded 8 E.H.P. The rope lay for a considerable part of its total length of 1·25 mile in water. The leakage of current, inevitable in a pit, decomposed water at various parts, and the iron at the junction to the copper return at the motor corroded rapidly. The trouble was recognised and caused no difficulty; but if the pit had been gaseous, it is probable that an explosion would have resulted.

A bare separate return, if justifiable at all, can only be so on account of cheapness; but the apparent saving is in most cases more than counterbalanced by after troubles.

If, however, a system of concentric mains be used with the outer conductor in metallic contact with iron or steel wire armouring, the conditions are altogether different; and probably as great an immunity from danger due to a broken conductor can be obtained by this arrangement as by any of the patented safety cables.

There are two classes of bare return concentric cables in use. They are shown in Figs. 106 and 107. The former has a lead covering, which is squirted around a copper conductor, the two together forming the outer or return circuit. Armouring can be applied outside, and so add to the conductivity while protecting the soft lead, whose chief function is to keep water from the insulation between the centre and outer conductors.

The second class is cheaper, and the return circuit is formed simply by the armouring, which is placed directly upon the insulation. It is only suitable for use in dry places, where it will give good results. (*See* Fig. 107.)

The chief advantages offered by these cables, in connection with mining work, is the security they give against *external* sparking, and their mechanical strength, owing to which they may be stapled to rough walls, like gas barrel.

There are also conductors which may be collectively classed as "safety cables." In all of them the object is to entirely obviate sparking at the point of rupture when an active conductor is cut in two. The general method is to provide a small auxiliary cable in parallel to the main conductor. This, in the event of a fall cutting the cables, is arranged to break either *before* or *after* the main conductor is broken; and in each case actuates a magnetic cut-out which opens the main circuit. The idea will be best understood by reference to some of the better known solutions of the safety-cable problem.

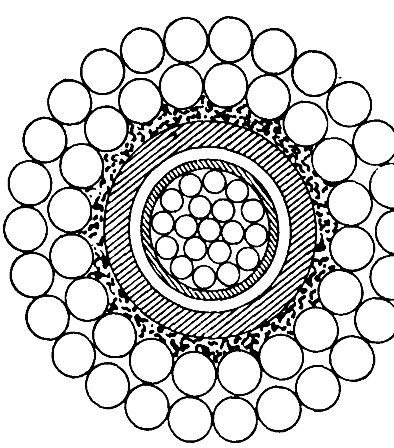

Fig. 106.—Bare return Concentric Cable. The return consists of a spiral of sheet copper under the lead, the lead and the steel armouring.

Mr. Ll. Atkinson, of Messrs. Easton, Anderson and Goolden, was the first to patent a cable of this class. It is not designed for concentric wiring, and hence two wires are required for each circuit. The cable (*see* Fig. 108) consists of two parallel conductors, insulated from each other excepting at the main terminals of the circuit to be protected. The current therefore is in the same direction in each conductor. The outer, which is designed to carry the larger part of the current, is of any ordinary make. The inner is constructed of fine wire in the form of a continuous cylindrical coil, the outer diameter of which is covered by insulation, and forms the core around which the main conductor is laid. It is assumed that when a stone falls on the cable the outer conductor, offering much resistance, will be cut through; but the

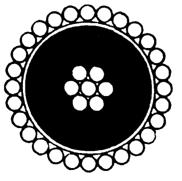

Fig. 107.

loosely coiled centre conductor will be simply drawn out of the insulation. The entire current will then pass through the fine wire, and blow a magnetic cut-out in the engine-room, or other convenient place; the arc being thus transferred from a possibly dangerous spot to a safe one. The efficient action of this cable depends upon two conditions—

1. Perfect insulation between the inner and outer conductor.

2. The continuity of the fine wire circuit being preserved during the fall.

In order to prevent an accidental contact between the two conductors interfering with the safety of the cable, the inventor provides a resistance in series with the fine wire at its negative end, so that the fall of pressure is less along the inside than along the outside. The result is there is always a difference of pressure between the inner and outer conductors at each part of the cable. And a short circuit between the two at any point causes an increase of current in the fine wire which operates the magnetic cut-out.

It may also be reasonably questioned whether a fall which is sufficiently heavy to cut a stout cable in two, will not sever the fine conductor before the spirals have time to draw out.

Generally it is found that cables hung lightly with plenty of slack are dragged down and buried without suffering any damage other than slight surface abrasion; but if they are firmly fixed they may be cut through as if with a knife.

In recent installations a small separated insulated wire has been hung (beside the main conductor) with a few spirals twisted at intervals so as to allow a ready increase of length in the event of a fall, or any undue strain. This is found to be cheaper than the compound cable, and to give equally good results. It should be mentioned that Mr. Atkinson regards the cable as of more importance as a preventative against firing timber from arcs than as an absolute means of preventing sparks. The author is in accord with this view. For the time

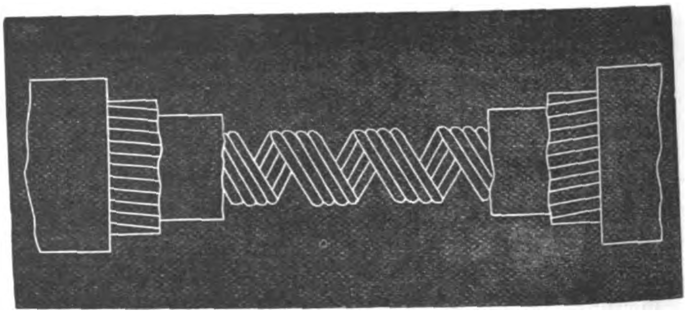

Fig. 108.—Atkinson Safety Mining Cable, showing the outer conductor cut through, and the inner one drawn out.

taken to move the detaching mechanism on the surface will chiefly determine the spark at the break in the cable, though its effect is limited by the resistance of the unbroken fine wire in parallel with the main wire.

The Charleton cable, patented by Messrs. R. J. Charleton, of Newcastle-on-Tyne, is of similar make, but the inner conductor is merely a small wire about No. 18 S.W.G. The currents in the two conductors are in the same direction. The action depends upon the fine wire breaking *before* the large one, when a magnetic cut-out is designed to open the main circuit. Successful working depends upon the maintenance of the insulation between the two circuits, and also upon the time required to move the magnetic cut-out levers. If this be comparable to the period of time elapsing between the cutting of the two cables it appears doubtful whether sparks would not occur almost simultaneously at the break and the cut-out. The problem is complicated by self-induction and capacity, which under

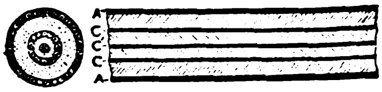

Fig. 109.—Sectional View of Nolet Safety Cable. A, Armouring; C, Main Cable; C[1], Auxiliary Conductor.

suitable conditions might seriously affect the *time* required to open the cut-outs after the breakage of the main conductor. It would be easy however to experiment for any particular case.

Another interesting safety cable is the invention of M. Nolet, engineer of the Cockerill Company, Seraing, in conjunction with M. Jasper, of Liége, and has been applied to several coal mines in Belgium. It provides for a small wire insulated and built into the cable, as in the Charleton cable, but the currents in the two circuits are in opposite directions. A sectional view showing the method of construction is given in Fig. 109.

The fine wire is coupled up as shown in Fig. 110. The function of the small wire circuit is to close the main circuit through the two magnetic cut-outs (one to each of the mains). Therefore, in the event of a breaking of the fine wire, the cut-out will operate and open the principal circuit.

Digitized by Google

M. Nolet has recognised that repairs to cables, as generally constructed, cannot be properly carried out without the use of soldering irons, which are inadmissible in a mine. To provide for this contingency his cable is made in short lengths, each section being provided with metal couplings for both of the conductors, as shown in Fig. 110A. The rings for the subsidiary wire are shown at C′, and those for the main conductor at C. The couplings are made to fit together with easy friction, and are so arranged that a sliding movement of about one quarter of an inch is sufficient to open the auxiliary circuit, while a considerable displacement is required to uncouple the outer conductor. The joints are protected by India-rubber tubes.

The construction appears to admit of a *certain* time interval between the opening of the main circuit, and the lifting of the magnetic cut-out, and also provides a ready means of repairing a damaged section. But the cable must be costly, and a slow

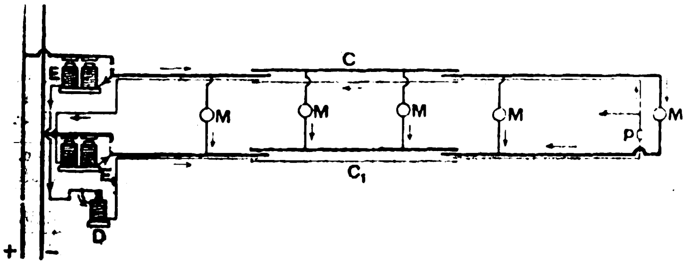

Fig. 110.—Diagram of connections of Nolet Safety Cable. C, main cable ; C_1 auxiliary conductor ; E and E_1, magnetic cut outs ; M, motors. Large arrows show direction of main current ; small arrows that of the shunt current.

movement of the measures, throwing weight on the cable, might interrupt the auxiliary circuit unnecessarily. And it may be questioned whether the device would have time to act in the event of a fall shearing the cable instantaneously, as sometimes occurs.

In the author's judgment, none of these safety conductors give more security than that obtainable with an armoured concentric one buried in the floor or suspended loosely, and with plenty of slack between the supports.

If a fall occurs, it will be brought down and buried. If the armour and outer conductor are cut through, the incision must first take place on one side, and then most probably the severed strands of the outer conductor will be pressed against the inner conductor, and so blow the magnetic cut-out without opening the circuit; because the bottom half of the outer conductor cannot be cut through until the top half is brought into contact with the inner one. The truth of this can be easily demonstrated by cutting the cable through with a cold chisel and hammer.

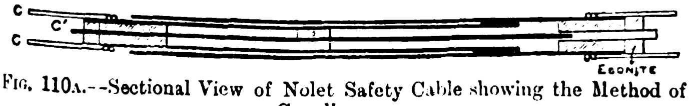

Fig. 110A.--Sectional View of Nolet Safety Cable showing the Method of Coupling-up.

Success lies in hanging the cable so loosely that it cannot be cut through instantly. If this occur, it is doubtful whether the two conductors would always be jammed into good contact by a sudden blow, and so a spark might occur coincidently with the blowing of the magnetic cut-out.

The danger of firing gas through a broken cable is very remote, however. There is, so far as the author knows, no authentic instance of this having occurred, although the possibility is sufficiently evident.

The fact is that cables are not usually run in roads with "weight" on them for obvious reasons, and where it is unavoidable, sufficient slack is allowed to prevent the nuisance of frequent repairs, quite irrespective of the risk of causing an explosion, and, therefore, broken cables are rare.

With the gradual extension of electric work in coal mines for driving portable as well as stationary machines, the risks from this cause will be increased, and it will be wise to recognise the danger and adopt the simple and efficacious remedies suggested by experience. This is specially desirable with new plants.

(To be continued.)

THE "PRACTICAL" WIRING CHART.*

BY A. G. SANDERS, A.I.E.E.

This chart, which is published as a supplement to the present issue, shows at a glance the relations between "S.W.G," "Sectional Area," "Current," "Current Density," "Loss in Volts," and "Weight"; between area in square inches and square millimetres; between solid and stranded cables; and also enable the horse-power lost per mile to be readily found.

The curves are calculated for Imperial Standard Wire Gauge, copper being taken at 98 per cent. purity (Matthiessen standard).

1.—"S.W.G." "Area and Weight."

The relations between S.W.G. Area (in square inches or square millimetres), and Weight in pounds per mile of conductor is found by following any desired size of conductor vertically upwards until the required scale is cut in the lower lines.

2.—"Current Density" and "Loss in Volts."

For any known "Current Density" to find the "Loss in Volts" for any given distance.—If the current density is found in column 2, then column 3 gives the loss in volts for a point 1,000 yards distant (*i.e.*, 2,000 yards of cable, lead and return). Say the distance is 400 yards and current density 1,000 amperes per square inch. Look out in the top line (scale of yards) for 400, follow vertically downwards until the diagonal density line 1,000 is cut, then horizontally to the right, and loss in volts from column 3 is found to be 20.

3.—"Density," "Current," and "Horse-Power lost per Mile."

The "Current Density" and "Current" being known, to find the "Horse-power lost per Mile of Cable."—Find required density in column 2, and corresponding "constant" from column 4; multiply this by the given current, and the result is the horse-power lost per mile. (Thus, at a density of 1,500 per square inch the constant is 0·0897, say the current is 40 amperes, then $0·0892 \times 40 = 3·568$ H.P.)

Also by proportion for any other length.

4.—"S.W.G." "Current" and "Current Density."

(A) *The "Current" and "Current Density" being known, to find the Correct "Size of Cable."*—(Say the current is 20 amperes, and the current density to be 800 amperes per square inch.) Look out 20 amperes in column 1, follow horizontally to right until the diagonal line 800 representing current density is cut, then vertically downwards to bottom line, when the nearest sized cable is found to be 19/19 S.W.G., or No. 7 solid.

If the area is required instead of size of cable this is given immediately above.

(B) *The "S.W.G." and "Current Density" being known, to find the Correct "Current."*—(Say the cable is 7/16 and density 1,300.) Find 7/16 in bottom line, follow vertically upwards until the diagonal density line 1,300 is cut, then horizontally to left, when in column 1 the current is found to be 30 amperes.

(C) *The "Current" and "S.W.G." being known, to find the "Current Density."*—(Say current is 30 amperes, and the cable to be used 19/20 S.W.G.) Find current 30 amperes in column 1, follow horizontally to the right until the vertical line representing 19/20 is cut, then diagonally to column 2, when the current density is found to be 1,500 amperes per square inch.

5.—"S.W.G." "Current" and "Loss in Volts."

(A) *"Current" and "S.W.G." being known, to find the "Loss in Volts," or "Horse-Power," for any given Distance or Length.*—Take the same case as above, but follow diagonal to column 3, which gives the loss in volts for a point 1,000 yards distant (*i.e*, 2,000 yards of cable) as 75 volts. If the distance is any other, say 200 yards, find 200 yards in top line, follow vertically downwards till diagonal density line 1,500 is cut, then horizontally to the right and loss in volts from column 3 is found to be 15 volts.

By following diagonal 1,500 to column 4 a constant 0·0897 is found, which, multiplied by the current, 30 amperes, gives the horse-power lost per mile as 2·676. Also by proportion for any given distance.

* Copyright; all rights reserved.

Digitized by Google

(B) *The "Volts lost" for any Distance being known, and also the "Current," to find the "Size of Cable."*—Say the distance is 500 yards, and loss in volts to be 50, with a current of 20 amperes. In top line find 500 yards, follow vertically downwards until horizontal line giving 50 volts in column 3 is cut, find nearest diagonal to point of inter-section, which gives the current density, in this case 2,000; follow this diagonal either up or down till it cuts the horizontal line giving 20 amperes from column 1, and then vertically downwards to the bottom, when the nearest size of cable is found to be 7/19, or No. 11 solid.

(C) *The "Volts lost" for any Distance being known, and "Size of Cable," to find the "Correct Current."*—Take the above case. Proceed as before, and find the nearest diagonal to point of intersection, viz., 2,000; follow this diagonal up or down until the vertical line giving size of cable is found, 7/19 in this case, then horizontally to left, and the current is found to be 18 amperes (from column 1).

THE APPLICATION OF SMALL-POWER ELECTRIC MOTORS.*

BY DOUGLAS T. HEAP AND ARTHUR C. HEAP.

As the field for the use of electric motors is such a wide one, the majority of the electric supply companies have made a reduction in the price of current required for this purpose. The plan adopted by the St. Pancras Vestry to induce customers to apply motor power, so as to increase the company's day load, is novel. Fig. 1

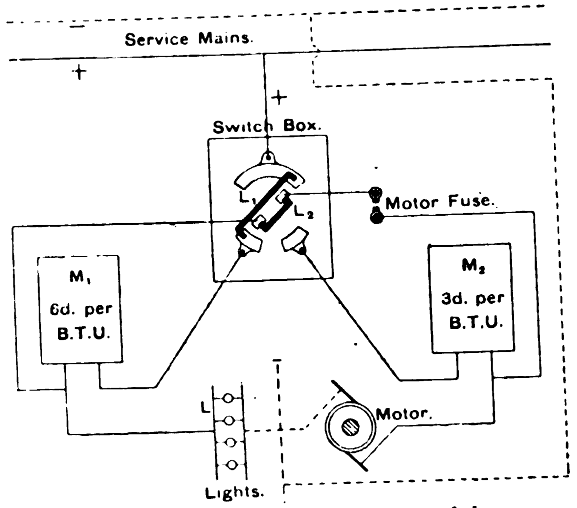

Fig. 1.—Supply to Motors at reduced rate of charge.

shows the connections, general arrangement of the switch, and the method of introducing the meters. It will be seen that there are two positions of the switch handle for the 6d. and 3d. current respectively. Corresponding to these there are fixed meters M 1 and M 2. Externally the two positions of the handle show the rate at which the power supply will be charged, while internally a compound switch bar, having two separate contact levers, L 1 and L 2, insulated from each other, but rigidly connected together, takes up the position given to it by the handle. The cross service wire enters at the upper portion of the switchbox, and is connected to the quadrantal contact in connection with the outer lever L 1.

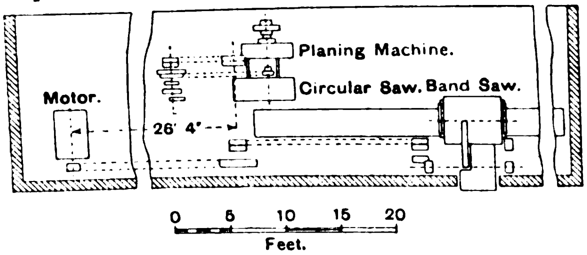

Fig. 2.—Electrically driven Saw Mill, Tring Park.

This, when on the left hand bottom contact, causes the current to pass through the meter M 1. After passing the meter, the current splits up between the lamp circuit L, and the power circuit, the path to the latter being through the smaller lever L 2, through the motor fuse, and by another T-joint, to the power terminals. For the day supply of power the handle is reversed, when L 1 will connect the cross service wire to the meter M 2, disconnecting the main lamp circuit and the smaller lever L 2. It is in this position that the special supply is given at the reduced rate, and the Vestry have arranged for a small number of lamps to be supplied in parallel with the motors where such lamps are incidental or necessary to the work being done by the motor plants. The main lighting, however, can only be obtained when all the supply is paid for at the 6d. rate.

After dealing with the capabilities and characteristics of series, shunt, compound, and differentially wound motors, the authors give the results of some tests of existing plants.

Some difficulty was experienced in getting these figures together, and the results may not appear so good as would have been expected, if efficiency only is taken into account; but the all-round results will be found to be favourable. For arriving at the cost of running, the price of a Board of Trade unit has been taken at 6d. in each test; this is about the maximum charge. The cost given is of the power only.

Test 1.—Crompton Compounded Motor Driving Capstan. Tested at Crystal Palace Electrical Exhibition.

Current, 45 amperes; pressure, 110 volts; revs. per minute, 1,050.

Load.	Volts.	Amps.	Revs. of capstan per min.	Brake horse-power.	Electric horse-power.	Efficiency. Per cent.	Cost of power for 1 hr.
							pence.
Motor only ...	101·25	6·50	...	...	0·88	...	3·95
Motor with gearing	104·20	6·75	...	...	0·94	...	4·25
¼ Load........	104·20	11·50	56·0	0·68	1·60	42·38	7·20
½ Load.........	101·25	20·40	54·5	1·93	2·77	69·80	12·30
¾ Load.........	97·75	31·00	52·0	3·00	4·07	73·80	18·10
Full load......	101·00	43·7	51·0	4·48	5·93	75·00	26·00

This plant started without any trouble at half and full load. The efficiencies obtained will be found to compare very favourably with those given for hydraulic capstans by Mr. John T. Corner in 1892 at the Portsmouth meeting of the Institution of Mechanical Engineers. It was stated that at full capstan power the percentage of main engine power at the capstan engines was 40 per cent.; but when the load was reduced to one-third of the full load the hydraulic efficiency fell to 22 per cent.

Tests 2, 3, and 4; Saw Mill Plant. Thomson-Houston Shunt-wound Motor of 15 B.H.P. Tested at Tring Park. (See Fig. 2.)

Test 2.—Driving Ransome 42-in standard band saw.

Speed of saw (light), 3,428ft. per minute; feed of material, 4ft per minute; gauge of saw, No. 20 S.W.G. (0·036in.).

Load.	Volts.	Amps.	Revs. of motor pr min.	Speed of saw, feet pr. min	Time taken for cut, min.	Electric horse-power.	Cost per foot of timb'r cut, penny.
Motor light ..	153·00	12·0	1,468	...	...	2·46	...
Driving countershaft	130·00	28·0	1,370	...	...	4·85	...
Driving machine thro' countershaft	128·25	42·0	1,242	3452·5	...	7·6	...
Cutting 9in. deal 21ft long	127·20	53·9	1,258	3382·0	5	9·2	0·16
Cutting 4½in. oak, 4ft long	130·00	48·0	1,295	3584·0	1	8·4	0·15

Test 3.—Driving Ransome 30in. Circular Saw.

Gauge of saw, No. 11 S.W.G. (0·116in.). Peripheral speed of saw (light) 10,895ft. per minute. Feed by hand 13·3ft. per minute.

Load.	Volts.	Amps.	Revs. of motor pr min.	Revs. of saw pr min.	Time taken for cut, seconds.	Electric horse-power.	Cost per foot of timber cut, penny.
Driving saw (light)	132	38·25	1,300	1,388	...	6·78	...
Cutting 9in. deal 10ft long	122	105·00	1,160	...	45·0	17·10	0·09
Cutting fir ...	124	105·00	1,178	...	1·5	17·40	...

It will be seen from Fig. 2 that the motor was not in any of the tests driving direct on to the machine, and therefore the power taken to drive the shafting (2·5 E.H.P.) should be deducted if it is desired to ascertain the actual costs. The authors considered it best, however, to give in the tables the figures recorded at the time of the test, so that any misunderstanding might be avoided. The tests have been repeated since the paper was read, and for all practical purposes, the same results have been obtained.

*Abstract of a paper read before the Junior Engineering Society.

Test 4.—Driving Ransome Wood-Planing Machine.

Two blades, 12in. long; feed, 20ft. per minute (approximately); revolutions of spindle, 3,430 (about) per minute.

Load.	Volts.	Amps.	Revs. of machine per minute (approximate)	Time taken for planing, minute.	Electric horse power.	Cost of planing, penny.
Running light	138	35·0	3,432	...	6·47	0·702
Planing $\frac{3}{16}$in. off 9in. deal 19ft. long...	138	50·8	...	1	9·40	...

Test 5.—Crompton Series-wound Motor of 3 B.H.P. driving Hoist.

Load.	Volts.	Amps.	Speed of lifting ft. per min.	Total weight raised, cwt. lb.	Electric horse-power.	Cost of power for 1 hour, pence.
Running light	99·5	6·5	120·0	...	0·86	3·87
Lifting 1 cwt. 14lb.	99·5	8·0	92·2	1 23½	1·06	4·77
Lifting 2 cwt. 16lb	99·5	10·5	80·0	2 25½	1·40	6·27

This plant is very compact, and is used for hoisting coal into a bunker on an upper floor, from which it is fed through hoppers into the stoke-hold. The motor drives through a worm wheel and single reducing gear, on to the drum of the hoist. With it a ton of coal (in 1cwt. sacks) can be raised in about 10min., including the time taken for hitching the sacks on and off.

Test 6.—Statter Motor of 2 B.H.P. driving Chaff Cutters.

Current, 14 amperes; pressure, 100 volts; revolutions per minute, 1,800

Load	Volts.	Amps.	Revs. of chaff cutter per min.	Time taken for cutting, hour mins.	Trusses cut.	Electric Horse Power.	Cost per truss.
Driving counter shaft	100	4·0	...	...	...	0·538	...
Driving chaff cutter light through countershaft	100	5 0	...	...	...	0·67	...
Driving chaff cutter at work	100	7·6	115·6	1 35	9	1·02	0·8d.

The comparative inefficiency of this plant is partly due to the amount of countershafting being driven, from which two other machines were being at the time of the test run light. Two men were required for working this plant.

Test 7.—Crompton Shunt-wound Motor, of 2 B.H.P. Driving Meat-Chopping Machine.

Current, 25 amperes; pressure, 100 volts; revolutions per minute, 1,520.

Load.	Volts.	Amperes.	Revs. of motor per min.	Revs. of machine per min.	Meat cut, lb.	Time taken for cutting, mins.	Electric horse-power.	Total cost, pence.	Cost per lb. meat cut, penny.
Driving counter-shafting...	101·5	5·0	1,400	...	...	...	0·77	...	...
Driving one machine light.	101·0	9·0	...	...	...	...	1·22	...	...
Driving two machines light	100·5	12·0	...	...	...	...	1·62	...	...
Driving one machine when cutting	99·6	15·6	1,379	272	110	15	2·08	2·25	0·02
Driving two machines when cutting	99·00	20·0	1,370	...	...	...	2·63	...	...

In this plant the motor drives on to a 1½in. shaft, from which the two machines are run. One man can easily attend to them.

Test 8.—Electric Motor Operating Riveting Machine.

General Description of Machine.—The riveting machine consists of a C-shaped steel frame, with long arms, 18⅞in. gap, so that the riveter can be worked on plates, girders, &c. The depth of the frame is 31½in., and the total weight of the machine is 2,204lb. It has two suspension rings, one for use when riveting horizontally, the other when riveting vertically. Two men are required to work the machine, a third heating and carrying the rivets. The time occupied in closing a soft steel rivet 1in. diameter was from 6sec. to 8sec. The pressure indicated by the gauge was 2,845lb. per square inch, the corresponding pressure on the rivet being 89,586lb., or nearly 40 tons. The machine is capable of putting in 80 to 100 rivets per hour. The rivet steel has a tensile strength of 28·5 tons per square inch.

Tests 9 and 10.—Electro-Magnetic Drilling Machines.

General Description of Machines.—These machines, the invention of Mr. Rowan, are made up of three principal parts—the holding-on magnets, the motor, and the drill. The drill is passed through an opening in the centre of the yoke, thus distributing the thrust of the drill over the two magnets. The feed of the drill is performed by a hand-wheel. The motor is usually wound for a 100-volt circuit, and when working the drill, and exciting the holding-on magnets, requires a current of 11 to 14 amperes (about 1·5 to 2 E.H.P.). It is fixed to the framework of the machine, the reduction of speed being obtained by means of gearing as shown. The machines are made in several sizes, some drilling to ½in., some to 1in., and others to 1¼in.

Results of Tests.—(9) At Portsmouth Dockyard, on H.M.S. "Royal Sovereign," 16 holes 1$\frac{3}{16}$in. diameter, through 2⅝in. steel plates were drilled in two hours, including the moving and setting of the machine. (10) At Messrs. Lindsay, Burnet, and Co.'s Boiler Works, Govan, the comparative cost of drilling 56 holes in a furnace tube, by hand labour, and by the electro-magnetic drilling machine was as follows:—

By Hand Labour (piecework)	s.	d.	*By Electro Magnetic Drilling Machine*	s.	d.
took 9½ to 10 hours.			took 3½ hours.		
56 holes at 1s. 4d. per doz.	6	2½	Use of machine at 9d. per hour	2	7½
			1 man at 6½d. per hour	1	10¾
			1 boy at 2¼d. „		7⅞
	6	2½		5	2⅛

These machines when used in conjunction with an electric rivetter, on bridge and similar work, ought to show a considerable saving. The results given under Tests 8, 9, and 10 were supplied by the respective makers of the machines.

Advantages of Electric Motors compared with other kinds of Power Machines.—In comparing the efficiencies of electric motors with other kinds of motive power, such as gas engines, hydraulic engines, &c., it should be borne in mind (1) that an electric motor is only using power as long as the switch is on, and yet it is always available at a moment's notice; the switching on and off being a very easy operation, the waste is reduced to a minimum in careful hands. (2) Since there are very few running parts, the saving in oil consumption is considerable. (3) That there is no heating the pits by gas jets during the winter months.

ON THE ELECTROLYTIC SEPARATION OF GOLD FROM SILVER.*

BY C. SCHNABEL.

At the works of the S. Louis Smelting and Refining Company an electrolytic method of refining has been substituted for the method of parting by sulphuric acid in the treatment of auriferous silver containing $\frac{6}{1000}$ of gold (28·8 grains per pound troy). The silver is cast into plates measuring 10 by 8 by 2½in., two of which are placed together in a linen bag to form one anode, with a rolled plate of fine silver for a cathode. The dissolving vessels are wooden vats, divided into seven cells, and rendered impermeable by a coating of bitumen, each vat containing 70 pairs of electrodes arranged in series. The electromotive force required for each bath is 1½ volt, with a current of 350 amperes per square metre, which is furnished by a dynamo of 100 volts and 200 amperes driven by a 30-H.P. Westinghouse engine. The electrolyte used in the first instance is water containing one-tenth per cent. of nitric acid, which is made up with very weak solution of silver nitrate as the operation progresses. The anodes are entirely dissolved in from 30 to 40 hours; the reduced silver separates in a crystalline form, shooting across from the anode to the cathode, so that short circuiting very frequently occurs. To meet this difficulty an apparatus is used for scraping the deposit off the cathodes at intervals, which, at the same time, keeps up the circulation of the solution in the bath. The deposited silver so removed falls to the bottom of the bath into boxes with double bottoms, perforated and covered with linen, for collecting the precipitate, which is removed once a day. The finely divided gold is kept back in the anode bags, where it is allowed to accumulate for a week before cleaning out. It is then boiled with nitric acid, washed, dried, and melted with a little sand or borax, giving a bullion 999 fine. The silver, after washing and drying is found to be free from gold, and assays 999·5 fine. The silver nitrate obtained from the final treatment of the gold is used to keep up the bath to the proper strength. At St. Louis 933 kilograms silver (about 30,000oz.) are parted by this method daily, and at Pittsburgh a still larger plant of 40,000oz. capacity is in use. At the latter place the finely-divided gold is melted with a small quantity of silver before being subjected to the final boiling with nitric acid.

STEEL-PLATE PORTRAITS

Of Willoughby Smith (out of print); W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday (1s. extra); Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; and Mr. Alexander Siemens, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

SPECIAL NOTICE.

With this week's issue of "THE ELECTRICIAN" is published (Gratis to Subscribers) a Large Sheet "Practical" Wiring Chart. Complaints of non receipt should be sent to the Publisher at once.

SMALL MOTIVE POWER.

The rental of a "Floor with Power" is a very common occurrence in the industrial north country, the supply of power usually being derived from a shaft-end poked through the party wall or a strap passing through the floor. In the majority of cases the owner of the engine can make a pretty accurate guess as to the amount of power that is likely to be consumed by the tenant, from the number and size of the looms which the latter puts in, and such refinements as transmission dynamometers or meterage of any kind are, of course, undreamed of. The common practice is to charge an annual rental of £10 per reputed horse-power demanded, and the tenant is left to make the best or the worst use of it according as he pleases. Some of the problems of power rental have recently been discussed by M. V. DUBREUIL, in a Paper read before La Société Industrielle du Nord de la France. Taking the case of a man who has 100 H.P. to dispose of, the power being developed by a simple steam engine of good type, and basing his calculations on French prices, which in some respects differ from the English ones, M. DUBREUIL finds that the annual expenses of the owner will amount to £816. Adding a small amount for profit, the rental per horse-power should be £9. Unfortunately, the power consumer will only be able to utilise some 45 per cent. of the power for which he pays; so that, in M. DUBREUIL's opinion, the annual price paid for a useful horse-power will amount to £20. The comparison between the price of

Digitized by Google

power obtained in this way with the price of power derived from central stations has frequently been made; the most recent, if not the most exhaustive, series of comparisons having been made by Prof. W. C. Unwin in his Howard lectures before the Society of Arts. In making the comparison with power derived electrically from supply mains, the simplest plan is to assume that the power is metred on the power tariff of 3d. per unit, adding a proper charge for interest on the cost of the motor and for depreciation. In cases where the motor would be required to develop full power for only 1,000 hours per annum, the cost of 1 H.P. will be found to be slightly under £10 per annum. But if the motor is run at full load during an eight-hour day, the price to be paid for a horse-power per annum will reach nearly £25. In most cases the electromotor could be applied to its work much more efficiently than could the end of a shaft poking through the wall, or even a belt coming up through the floor. In this way the power could be used much more economically, resulting in a more favourable price per E.H.P. actually utilised. In fact, in many cases the cost of the useful power would be but slightly less than the cost of power at the meter; while when obtained mechanically it is nearly double. In many other cases the question of efficiency is of small importance as compared with the enhanced convenience, portability, speed, &c., of the electric motor.

In this connection we cannot do better than refer our readers to the interesting Paper, by Messrs. D. T. and A. C. Heap, on "The Application of Small-Power Electric Motors," an abstract of which we publish this week. In such work as driving a capstan, for example, some figures about which are given, a high mechanical efficiency is no more wanted than it is in drawing teeth. What is wanted is force, and plenty of it, properly applied; besides which it is desirable to have a high *plant efficiency*—that is to say, a large capability comprised within a small compass. The convenience of being able to work as readily and as well at low loads as at full load is also of some importance. The same remarks apply to elevators, for which the convenience of electric motors is superior to that of hydraulic motors, where the power required is small. When something more efficient than worm gear can be adopted, the relative advantage of the former will be even greater than it is now. In many of the applications of electric motors the speed of the machine is very high, and it is very convenient to be able to couple the motor directly to its work. In Test 3 of the Paper just referred to, for example, a 30in. circular saw driven by a 15-H.P. motor was tested. Gearing was used, the speed of the motor being 1,300, and that of the saw 1,388 revolutions per minute, running light. In such a case direct coupling should have been the simpler, as it certainly would have proved the more efficient, plan. This, indeed, is one of the most important aspects of the problem of adapting electric power to the driving of machine tools. Not only must the electric motor be specially designed for the class of work it is to undertake, but, in our opinion, the machine tool should also be specially designed, so that it may be directly coupled to the motor. Gearing is a wasteful and clumsy makeshift in the majority of cases, and there are as many reasons for eliminating it from the machine-shop or factory as from the engine and dynamo room. The concluding tests (Nos. 9 and 10) are interesting as showing the superiority and relative cheapness of electrically-performed work over hand work. The tests relate to an electrical rivetter and drilling machine. The mode of estimating the cost of the electric drilling is not at all clear; but, granting that it was no less than the hand labour, the saving of time—3½ hours instead of 9½ to 10 hours—is of the highest importance.

REVIEWS.

Elementi di Fisica. By Prof. Antonio Roiti. Vol. II. Third edition. (Florence: Successori Le Monnier.)

Our Italian *confrères* are in the habit of putting forward the claims of their own language to be considered the most appropriate medium for the expression of scientific ideas. Without going so far as to endorse this claim, we may admit that the fellow-countrymen of Galileo have every reason to be proud of the readiness with which the Italian language lends itself to the terse and accurate exposition of the truths and conceptions of the exact sciences. The present work, which evidently aspires to be in Italy what Müller-Pfaundler's *Lehrbuch* is to Germans, and Jamin's *Cours de Physique* to French students, may be fairly said to be superior, both in scope and in detail, to any similar work yet published in the English language, although not up to the standard of the French and German works referred to. The second volume comprises light, and electricity and magnetism. The chapter on photometry might be enlarged with advantage. Rumford's and Joly's photometers are not mentioned, and Ritchie's name is misspelt Ritshie. The chapters on geometrical optics are, however, excellent, and form the neatest *résumé* of the subject we have yet seen. In the treatment of colour perception Koenig's curves might have been drawn with greater care. The word *rifrangenza* for refractive power distinctly scores for the Italian language. The chapter on the absorption of radiant energy includes calorescence, phosphorescence, fluorescence, a description of the radiometer and the photophone, and a brief summary of photographic theory, to which is added a paragraph on the colour-photographic process due to Lippmann (misspelt Lipmann). The discussion of polarised light is somewhat meagre, but is clear so far as it goes, and as accurate as can be expected with an almost entirely non-mathematical treatment. Passing on to Part VI.—"Electricity"—we find, as might have been expected, a full discussion of Galvani's and Volta's first experiments, and of the ensuing contact controversy. Of modern batteries, only a few leading types are mentioned. On p. 315 is given a very good and interesting map showing the magnetic elements for Italy during 1888. Magnetic shells are treated fully and effectively, with the freest use of symbols to be found in the book. Ewing's investigations on magnetic induction are done justice to as far as space allows; but when we come to the definitions of practical electric units we find the following curious passage about the "volta," the unit of E.M.F.:—*Gl'Inglesi la chiamano* volt: *ma a noi Italiani dovrebbe ripugnare di abbreviare così il nome del nostro celebre Fisico.* This deviation from the name fixed upon not merely by us *Inglesi*, but by the whole civilised world, including many eminent Italian physicists, is then atoned for by calling the unit of capacity the *faraday!* The rationalisation of the electrostatic and the electro-magnetic systems of units by the introduction of μ and k with their proper indices is not even referred to. On p. 431 we find Jablochkoff spelt Jablachkoff, and thus gradually come to suspect a certain carelessness in this manner of recognising foreign authorities, a suspicion which is enhanced by the name Ruhmkorff on p. 481, although we have seldom seen it spelt correctly, viz., Rhumkorff, even in English publications. The volume closes with a thoroughly modern account of Hertz's wave experiments, and a diagram of his original apparatus on the title page shows the importance attached to this youngest branch of electrical science. The illustrations are, on the whole, good and clear, though not as pretentious as those we are getting used to in some present-day text-books.

Electricity One Hundred Years Ago and To-day. By Edwin J. Houston. (New York: W. J. Johnston and Co.)

This book resembles Spenser's Faërie Queene, for it is almost beyond the power of man to read it through. It consists of a lecture, which, when delivered at Brooklyn, was no doubt intelligible and interesting; but "in preparing the lectures for publication" the author has "concluded to permit the text to remain substantially as delivered, preferring to

Digitized by Google

add in the way of footnotes whatever additional matter may be required, rather than to materially change the original matter or arrangement." In making this addition the text and the notes have become inextricably confused. The old-fashioned style of printing the notes all together at the end of the book is the only feasible method of arrangement of such notes as these. Seeing that they were of considerably greater importance than the text, both in interest and bulk, we began to read them through, ignoring the three or four lines of large type at the head of the page, but the editing is so bad that even this is impossible. The notes consist for the most part of extracts from old books, and certain anecdotes about Franklin, Muschenbroeck, Jacobi, Volta, &c. They are, in many cases, most interesting, and the author adds to their value by giving references to their sources in proper bibliographical form.

THE DAVY ARC LAMP.

A descendant of Sir Humphry Davy, the inventor of the first arc lamp, has recently entered the field as the inventor of a modern type of lamp, possessing features and details of design of which Sir Humphry probably never dreamed. We are enabled to give, this week, some diagrams of one pattern of the new "Davy" arc lamp. This particular pattern is designed

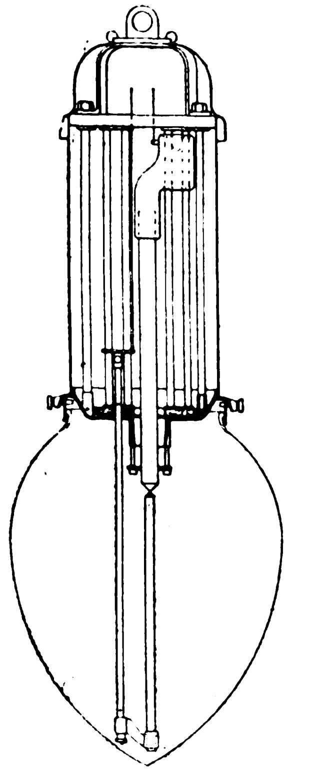

Fig. 1.

for burning a single pair of carbons, with either a continuous or alternating current of 5 amperes, and is specially adapted for interior and exterior lighting for shops and similar buildings. Larger forms of the lamp, for street lighting, are designed to carry two pairs of carbons; and Mr. W. J. Davy, the inventor, has constructed a modification of the lamps, suitable for special purposes, which carries and automatically burns no less than six pairs of carbons. The single and duplex lamps have been running for some time with the alternate current at Portsmouth, as well as in various parts of London; and a well-distributed and steady light appears to be maintained by them. In a trial which we recently witnessed of the multiplex lamp, the carbons having been arranged to fire off in quick succession, it was curious to observe the promptness with which no less than six successive arcs were formed with scarcely a flicker in the light. The utility of so many change-overs may not at first be quite apparent; but there are probably places where more than two pairs of carbons are required, or where the carbons must be exceptionally short.

Fig. 1 gives a longitudinal elevation of the single lamp, the solenoids and grip-brake being removed from the upper part. Both carbons are held in a travelling holder, the two travellers being connected by a flexible band passing over a fixed pulley at the top of the lamp. The upper carbon, in the continuous-current lamp, is made of about twice the section of the lower carbon, thereby ensuring a perfectly fixed position for the arc. In the alternate-current lamp the carbons are, of course, of the same diameter.

Normally, when the lamp is running, the flexible band is gripped by a friction-brake, the details of which are shown in

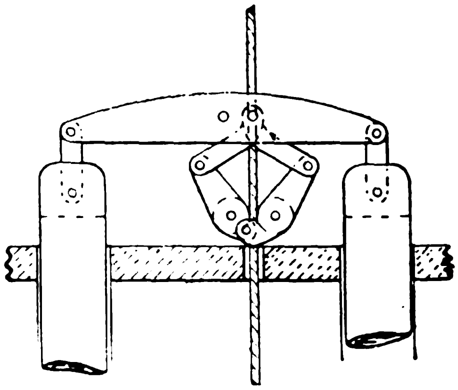

Fig. 2.

Fig. 2. The brake consists of four links, jointed together to form a flexible frame. The upper joint is coupled to the see-saw lever, which is rocked by the solenoids; and close to the lower joint the two jaws, which are designed to grip the band between them, are placed. Upon the rocking lever lifting the upper joint the linkwork extends in such a manner as to grip the band, and, on the motion of the rocking lever being continued in the same direction, the band on the gripped side is lifted, thereby separating the carbons and striking the arc. The see-saw of the rocking lever is regulated by the antagonism between a main solenoid and a shunt solenoid, this method of regulation being a common feature in all modern arc lamps. The mounting of these solenoids, with their cores and the grip

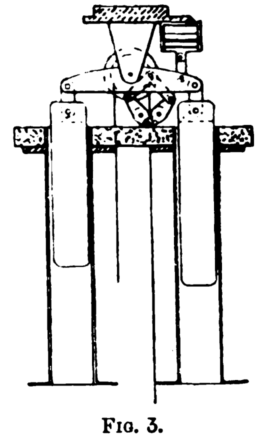

Fig. 3.

brake, is shown in Fig. 3. An air dashpot is fixed to the rocking lever to prevent too violent motion. Feeding takes place when the pull of the shunt solenoid preponderates over that of the main solenoid sufficiently to lower the right hand half of the rocking lever until the grip jaws gently release the band. The band then skids slowly between the jaws, and gives an even feed.

The compactness of this lamp is one of its salient features, and one which will render it useful where longer and heavier lamps would be unsightly; besides which, the simplicity and fewness of the working parts make the lamp cheap, durable, and easy of repair.

ON THE DAMPING OF BELL MAGNETS AND RING MAGNETS BY SURROUNDING COPPER.

In the American *Journal of Science* for June, 1894, Mr. Arthur Kendrick gives an account of some experiments made to determine the damping action of copper boxes on enclosed bell magnets. The conclusions are of great interest, and will be of value to those wishing to design galvanometers having this type of magnetic system.

The experiments were made with magnets of varying magnetic and inertia moments, and copper boxes of various shapes, and the results, where possible, are embodied in curves. In these curves the author prefers to use as his measure of the damping the ratio of one amplitude to the preceding one, rather than the logarithmic decrement. He makes an error, however, in stating that his damping coefficient is the reciprocal of the log. dec., and that the limits of the values of the log. dec. are ∞ and 1, as against 0 and 1 for his coefficient. In this he has confused the log. dec. with the decrement itself. Curves are first given showing the relation of damping to inertia with constant magnetic moment, and of damping to magnetic moment with constant inertia. These are given for boxes of various dimensions, and appear to show (*a*) that the damping increases rapidly with the magnetic moment; (*b*), decreases with increase of inertia; (*c*), increases with the thickness of the box; (*d*), decreases rapidly with the internal diameter of the box. They also show that the damping was much increased by adding a bottom to the box, although a disc alone held below the magnet had little damping effect. The thickness of the bottom had little influence on the damping, but the proximity of the magnet to the bottom had a large effect.

Brass boxes appear to be much inferior to copper, showing the great influence of the conductivity of the material of the box. Experiments were also made with non-cylindrical boxes and boxes with slits cut in their sides. With a cylindrical box having two sides planed flat so as to produce an oval exterior the damping was reduced, but the position of the longer axis was immaterial. Slitting the box has no effect when the slit is perpendicular to the plane of the magnetic axis, but has large influence when the slit is in that axis.

The author concludes by saying that the observations are not sufficient to establish a mathematical solution of the problem; but he appears to have overlooked the fact that some of the curves can be obtained mathematically. These curves appear to agree very fairly with theory.

THE MEASUREMENT OF THE PUPIL OF THE EYE.*

In connection with the subject of artificial lighting, the various causes which influence the diameter of the iris are of interest, as the efficiency of the eye, and hence of the system of lighting, is directly dependent upon the amount of the pupil exposed to the action of the light rays. Numerous instruments have been proposed for measuring the diameter of the pupil, but none of them can be considered very accurate. Great difficulties are encountered in the direct measurement of the diameter with a graduated scale, owing to the movements of the eye, and the close resemblance between the colours of the iris and the pupil in dark eyes, while even in light-coloured eyes the iris has often a darker border, which can easily be confused with the pupil itself. Parallax errors also arise owing to the distance between the pupil and the graduated scale.

Medical men have often used Follin's scales, consisting of a number of black circles, increasing in diameter from 1 to 13 millimetres, and placed upon a card. The size of the pupil is estimated by comparing it with the circle nearest in diameter. Follin also used to make the measurement by placing in front of the eye a glass micrometer scale, and the reading of the divisions was facilitated by the use of a lens as suggested by Halma Grand.

Lambert and Olbers observed the reflected image of the eye produced by a plane mirror, and measured the diameter of the image by means of a compass. Laurence and Galezowski used a graduated scale provided with two cursors, each carrying a hair. By sliding the cursors along the scale the hairs could be made to approach or recede until their distance was exactly the diameter of the pupil. Coccius observed the pupil through a lens of 74mm. focal length, placed in a box provided with three apertures, one for the eye of the observer, another for the eye being tested, and the third being a lateral opening for the purpose of illuminating a scale divided into half-millimetres fixed on the lower half of the lens. This lens is movable along the axis joining the two eyes, and the observer sees simultaneously the pupil and the image of the graduated scale reflected by a mirror. The observing eye is moved along the axis till the image of the eye under observation is sharply defined against the scale, and the diameter can then be measured.

Doijer used a Ramsden's eye-piece and a glass plate divided into hundredths of a millimetre, and placed at a distance equal to four times the focal length of the lens from the eye under observation, the lens being placed midway between them. The image under these circumstances has the same size as the object, and its diameter can be read off directly on the graduated scale.

Helmholtz has pointed out a most ingenious device which has been found useful for pupillometers. When any object is looked at through the line of separation of two plane-glass plates with surfaces in contact along one of their edges, two images are seen instead of one, the distance apart being dependent on the index of refraction, the thickness of the plates and the angle of incidence of the rays and the angle of inclination of the plates. These quantities are easy to measure, and when the two images are just in contact the separation is equal to the diameter of the object. Landolt has improved this rather complicated instrument by using two thin wedges of glass placed over each other, with their edges in contrary directions. These prisms are movable by means of an adjusting screw, which can be graduated.

All the above instruments are founded on the principles of physical optics. In 1856 Fick introduced an entirely new kind of instrument depending on physiological optics. The principle here involved has since been made use of by Robert Houdin and by Dr. Badal. It can be stated as follows. When two luminous points, the line joining which is perpendicular to the axis of vision, produce on the retina two circles of diffusion which just touch each other, the distance between the points is just equal to the diameter of the pupil. This can be proved as follows:—

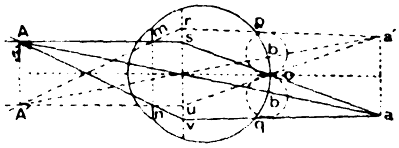

Fig. 1.

If the eye is looking at a distant object it is focussed so that the image of it is formed on the retina *p o q*. Nearer objects, such as A A', will not be focussed, and the light from one such as A will be distributed over a circle, *o b q*, on the retina. If *m n* is the diameter of the iris and if *r s u v* is the plane of the simple lens equivalent to the eye, then the lines of the figure show how the eye tends to produce an image of A A' at *a a'*, and that owing to the interposition of the retina two diffusing circles are formed. Now if *m n* is the same diameter as A A', the two circles will just touch at O, which is the focus of distant objects on the axis of vision, and which therefore receives all rays parallel to the axis. If *m n* is larger than A A the two circles will overlap, while if it is smaller the two circles will be quite distinct. By adjusting the distance A A' till the circles just overlap it is thus possible to measure *m n*, the diameter of the iris.

It may be objected to this proof that the eye cannot be regarded as a simple lens. It is really composed of a combination of lenses, the substances of which have different indices of refraction; and as the iris is within one of these lenses a magnification is produced which prevents the measurement made in this way being correct. The author of the Paper goes

* Abstract of a Paper by M. Charles Henry, entitled "Pupillométrie et Photométrie," appearing in recent issues of *La Lumière Electrique*.

Digitized by Google

fully into the question, and arrives at the conclusion that the image measured in this way is $1\frac{1}{7}$ times the true diameter of the pupil, and thus shows that it is necessary to multiply the measurement actually obtained by $\frac{7}{8}$ in order to get the true result. When this correction is made these pupillometers give a perfectly accurate result. They are simple in construction and rapid in action. The errors arising from parallax and from confusing the border of the iris with the pupil, which are so serious in most pupillometers, are entirely overcome in this.

The simplest form employed in the author's experiments was one due to Robert-Houdin, and is illustrated in Fig. 2. It consists of a shallow copper cylinder 12 millimetres deep, the front being provided with an opening and a small hole, *b*. A screen pierced with a small hole, *a*, and provided with an index, *c*, slides over this opening by turning about an axis, *d*, in the circumference of the circle. The distance between the two holes *a* and *b* can be read off on the scale by the index *c*. All lateral light can be shut off by the use of a dark cloth. Other instruments have been devised on the same principle. One due to Gorham consists of a metal tube closed at one end with the exception of a radial opening. A metal disc pierced with holes arranged radially in pairs at various distances apart is attached at the closed end of the tube in such a manner that it can be turned so as to present different sectors to the radial opening at the end of the tube. In this manner, by looking along the tube and turning the disc, two bright spots of light are seen, and the distance apart of the spots seen can be regulated by simply turning the disc. When two of the holes are such that the circles of diffusion touch each other, it is known that the distance

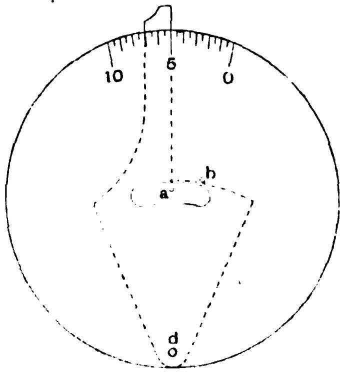

Fig. 2.

apart of these holes is equal to the diameter of the pupil. M. Gorham proposed to use this instrument as a photometer by measuring the size of the pupil when the tube is turned towards different lights. The distances of the lights were adjusted till the diameter of the pupil was the same whichever light was looked at, and it was assumed that under these circumstances the square of the ratio of the distances was equal to the relative candle-power of the lights. This assumption is, however, doubtful, as the contraction of the pupil does not depend merely on the intensity of the illumination. Before concluding the account of the various pupillometers yet devised the method of photographic records used in 1887 by Bellarminoff must not be forgotten. This scientist used a chronophotographic apparatus, by means of which the diameter of the pupil could be ascertained at any instant during the course of the tests. This method undoubtedly is the most accurate, but it is too complicated and costly for use.

As regards the direct action of light upon the iris, some experiments made by Brown Séquard in 1847 appear to prove that only the luminous rays have any effect, heat rays and chemical rays being inactive. The eyes experimented upon were those of fish and bratracians. They were extracted from the orbits immediately after death, and the pupils were found to contract on the approach of a candle, and to expand again in the dark, the effects being reproducible some times as frequently as 100 times in an hour. The interposition of a plate of alum did not alter these effects, showing they were not the result of heat rays. The persistence of the pupil movements, long after the nerves had lost all sensitiveness to irritation, seemed to prove that the action was muscular and not nervous. Moreover, utilising the fact discovered by Brücke that the cornea and crystalline of the ox and the rabbit absorb the violet and ultra-violet rays, light was allowed to fall on the eyes of frogs after having been previously filtered by passing through the eye of a rabbit. The pupillary contraction was found to take place just as before. All the evidence is thus in favour of the view that only the luminous rays are capable of producing the movements of the iris. Experiments of a like nature on human eyes are, however, still wanting, and it is to be hoped that some will before long be made.

Actual measurements of the diameter of the pupil of the eye have been very rarely made. Lambert, in his book on photometry published during the last century, gives a few measurements and conclusions founded on them. The principal of these conclusions is that if the eye be exposed to different degrees of illumination, the area of the pupil exposed does not vary inversely as the illumination, but in such a manner that the product of the illumination and the area exposed becomes less and less the feebler the illumination. M. Charles Henry is trying to reproduce these experimental results of Lambert with better and more reliable apparatus.

HEINRICH HERTZ.*

(*Continued from page 299.*)

The last research carried out in Berlin is entitled "On the Behaviour of Benzine as an Insulator and Absorber." All insulating materials exhibit in a greater or less degree the often very troublesome property of absorbing and retaining a portion of the electric potential acting upon them. In the older theories this process of "absorption" is represented by assuming that the electricity partially wanders from the charged condenser-plates into the insulating material between them, and is there retained. But it was soon observed that the property of absorption is essentially connected with want of homogeneity of material, so that homogeneous crystals, for example, exhibit the phenomenon only in a small degree. In order to obtain more definite results Hertz undertook experiments with liquids which can easily be rendered perfectly homogeneous, and he found in commercial benzine a medium which insulated sufficiently well for his purpose. It then appeared that the dielectric power of benzine increased under the continued action of electric forces. The cause of this was traced to the increase in the amount of suspended or dissolved impurities which were set free; under the influence of electric charges, therefore, the liquid is "electrically cleaned." It was evident, also, that the power of absorption decreased after this prolonged cleaning, so that this property must really be attributed to want of homogeneity. No migration of free electricity takes place, but the electric stress takes hold of the separate foreign particles embedded in the medium, and arranges them in a sort of strained or polarised condition. Hertz showed that this was the case by suddenly letting the liquid flow out of the trough which he had used as a condenser in these experiments, or by lowering into it two metallic plates connected with an electrometer, which clearly indicated the presence of this polarised state in the medium.

Although somewhat anticipating its chronological order I will here mention a short communication "On the Dimensions of a Magnetic Pole in Different Systems of Units," in which Hertz took part, although quite objectively, in the then burning question of the dimensions which should be chosen for electric units. He shows that the so-called "electro-magnetic system" is not more justifiable than the "electrostatic system," simply because it does not lead to want of agreement between the theories of Maxwell and Clausius; he then points out the cause of this want of agreement, and shows that the ratio of units in the two theories is exactly inverted if the magnetic measure of the current is taken as a starting point instead of the electric one.

We come now to the unique and splendid theoretical investigation of the year 1884, which is certainly the most important one in connection with the further development of Hertz's ideas, namely "On the Relations between Maxwell's Fundamental Equations of Electro-dynamics and those of Opposed Theories." We may characterise this as Hertz's greatest contribution to theoretical physics.

As the title itself indicates Hertz now declares himself definitely opposed to the orthodox theories of electric phenomena which at that time were put forward in Germany, and he passes over to the camp of Maxwell's followers. But why does he take this step? He

* Memorial Address by Prof. Hermann Ebert, delivered at the meeting of the Physical Society of Erlangen, March 7, 1894. Translated by James L. Howard.

Digitized by Google

was not attracted by the fact that in Maxwell's theory at that time the part which explained light as an electro-magnetic phenomenon was still shrouded with a certain degree of mystery. He was not allured by the wide perspective and the multitude of new problems towards the solution of which a research-loving mind would be attracted; no, it was after a prolonged struggle with his inward conviction that he freed himself from the old ideas which had become fast-rooted even in him. He proves, firstly, that the systems of equations of the older theories are incomplete; that from them certain members are missing, the absence of which even a supporter of the theory of distance-action would concede to be a defect. But if these terms are added the formulæ begin to be unwieldy and awkward; in place of finite expressions we have infinite series which certainly converge towards a finite limit, but which appear so opposed to nature that the dissatisfaction on arriving at such formulæ is not compensated by the fact that we at last possess the complete expressions for the observed phenomena. Hertz then obtains from the unwieldy formulæ a system of equations of great clearness and simplicity, a system which is immediately greeted as a known one in Maxwell's theory. The necessary improvement in the older theories leads, therefore, to that of Maxwell, and this must be chosen as the starting point in all further progress. But even Maxwell's formulæ are here expressed in a clearer form, and this is an important advance in the theory. Maxwell, free as he was, could not completely emancipate himself from the older views, and his formulæ possess a slight unwieldiness and want of simplicity, traceable to the fact that the fundamental idea of his theory is not yet logically and clearly expressed by them; they still contain traces of conceptions belonging to the older systems—rudimentary conceptions, as Hertz occasionally and significantly calls them. Hertz has definitely removed these rudimentary notions, thus clearly exhibiting the kernel of Maxwell's theory. Already in this Paper of 1884 we meet with that system of six partial differential equations which served afterwards as Hertz's guide along the tedious and devious path of his experimental researches.

Hertz had thus acquired new views from his theoretical considerations, and with this discovery in theory his life-work was indicated for him. He must now strive to prove experimentally the superiority of Maxwell's theory and to trace all the immediate consequences of it. That the task of finding out the best method was no easy one even for a Hertz we may infer from the fact that he was occupied during three years merely in preparing the necessary apparatus.

One of the most important consequences of Maxwell's theory was that disturbances of electrical equilibrium produced at any place must be propagated as waves through space with finite velocity; indeed, with the velocity of light. This was plainly a fact to work upon. If this propagation was to be traced through the space inside a laboratory the disturbances must be rapid, and if a definite effect was to be observed they must also follow each other at regular intervals; that is, periodically varying electrical conditions, or electric oscillations must be set up, the period of which would have to be very small so that the corresponding wave-length, taking into account the extraordinarily high velocity of propagation, should be only a few decimetres.

The method of exciting electrical oscillations was indeed known, and that of producing rapid electric disturbances had already been investigated in Helmholtz's laboratory. As far back as 1870 Von Bezold had actually measured the length of electric waves and observed their interference in wires, and yet some links in the chain were wanting. One, or rather two, further conditions were necessary. We are fortunate in possessing Hertz's own account of the origin of his epoch-making work. In the introductory notice to his collected Papers on electric waves* he gives a classically beautiful picture of the gradual advance of a genius in research, in which his modesty compels him to omit much that we ourselves must fill in, namely, the importance of his earlier work.

He tells us that his interest in electrical oscillations was originally awakened by the Berlin prize of 1879, which was to be awarded for an experimental proof of a relation between electro-dynamic forces and dielectric polarisation in insulators. Prof. von Helmholtz advised young Hertz to devote himself to this research. Hertz discovered, however, that the then known oscillations were too slow to ensure success, and he therefore gave up the research; but from that time he was on the look-out for everything connected with electrical oscillations. Consequently he immediately recognised the importance for his purpose of an observation which in itself appeared very trivial. One of those accidents occurred which often point the inquiring observer to the right path, and lead to important consequences. Hertz tells the story himself very neatly. In the collection of physical apparatus at Karlsruhe he found an old pair of so-called Riess's or Knochenhauer's spirals; short, flat coils of insulated wire, with the turns all in the same plane. Hertz showed them in lecture and performed experiments with them. He thereupon noticed that the discharge of a very small Leyden jar, or of a small induction coil, passed through the one sufficed to excite strong induced currents in the other, provided that a small spark-gap was inserted in the circuit of the first one. Hertz thus made the discovery of the "effective spark-gap" which rendered his later quantitative measurements possible. Although a spark discharge had previously been somewhat justly considered very complicated, and above all things a very variable phenomenon, and consequently experiments in which sparks played any part were usually looked upon as "impure" and regarded with suspicion, Hertz found a definite effect his, provided only the discharging condensers (his Leyjars, for example), must be of small capacity; and, above all things, the paths of the discharge were of simple form and short, not consisting of long coils of wire, as in the induction coil. If these conditions were fulfilled an electrical motion excited a perceptible electrical *resonance* in a circuit of similar shape and size to its own. We have here the real kernel of Hertz's discoveries, and I might sum up the experimental evidence of all later researches in the following sentences:—

1. If we allow small condensers with small capacities to discharge through short and simply-constituted circuits with a moderately long spark-gap, we obtain a sharply-defined discharge of very short duration, which is the long-sought-for sudden disturbance of electrical equilibrium. This was a discovery which could be foreseen by no theory, a newly-discovered property of electric sparks, on which, however, all the later work depends. But theory showed further that at the same time success was assured on the second point, since oscillations of the required period were obtainable; so that Hertz had now a powerful exciter of electrical vibrations.

2. Such vibrations are capable of exciting in another discharge circuit of like form resonance phenomena of sufficient intensity, even when the two circuits are separated from each other by great distances. Hertz had therefore found a receiver by means of which he could detect the waves produced by the exciter and propagated to any distance.

In the work which next appeared, "On very Rapid Electric Oscillations," we find him occupied with these phenomena; he is studying his apparatus, and gradually constructing and perfecting it. As an exciter of oscillations he uses wire rectangles or simple metal rods, to the ends of which metallic cylinders or spheres are connected; the exciter is broken in the middle by a spark-gap with small spherical knobs, between which the spark passes. The exciter is charged by an induction coil, the complicated form of whose discharge only plays a secondary part, and scarcely comes into consideration. The receivers are mostly simple rectangles of wire, likewise provided with spark-gaps; their length is so arranged that they show the maximum resonant effect with a given exciter, they are "electrically tuned." When a resonant vibration is set up in them, sparks pass across the gap, and the greatest length of the spark measures the intensity of the effect.

Such is the principle of the new and simple means which Hertz has introduced into the physical laboratory, and with which so many physicists are at present working in various directions, and endeavouring to penetrate into the unknown. It was owing to a strange accidental circumstance that these discoveries, and the later work of Hertz, met with immediate recognition rather than to their intrinsic value—how often the greatest discoveries remain long unheeded! Hertz found in his earlier experiments on electric resonance a phenomenon which attracted his notice by its definiteness and simplicity, and charmed him by its novelty and its inexplicable character. It was seen that the length and brightness of the resonator sparks were strongly influenced by the sparks in the primary circuit. If the latter were visible from the resonator spark gap they appeared small and hardly perceptible, but they became immediately larger and brighter as soon as a screen was placed between the two spark-gaps. In his work, "On an Influence of Ultra-violet Light on the Electric Discharge," he depicts in almost dramatic fashion how, by carefully thought-out experiments, he finally came to the conclusion that this singular action on spark discharges is traceable only to ultra-violet light. Many experimenters continued these researches and discovered remarkable new facts concerning them; indeed, Hertz introduced quite a new branch of experimental physics, that of the action of light on electricity. If these experiments did not immediately lead to the discovery of a closer relation between the two phenomena, they served to make Hertz popular, so that everything coming from him was eagerly read.

Few people, however, thought at that time that this pretty, though only subsidiary, effect was not the main discovery, or that we were on the eve of much greater conquests in the domain of electric oscillations. We find Hertz busy once more with his apparatus. In the following year appeared "On the Action of a Rectilinear Electric Oscillation on a neighbouring circuit." This was the most difficult and the most important of Hertz's experimental researches; it is often overlooked in descriptions of his work, and yet it forms a necessary step to the following conquests. Hertz had become familiar with the phenomenon of resonance; he had now

* "Electric Waves," by H. Hertz, translated by D. E. Jones. Page 1. (Macmillan.)

Digitized by Google

to deal with the propagation of oscillations through space. The apparatus was already furnished; as exciter he made use of a straight metal rod with a spark-gap in the middle and a spherical conductor at each end to give it capacity. When sparks pass rapid electrical surgings occur; we have a rectilinear oscillation whose effect is radiated out into surrounding space. As receivers he used tuned circles of wire, likewise provided with very small spark-gaps whose length could be measured with a micrometer. These were brought into all kinds of positions with respect to the exciter, and Hertz studied and measured the effects. These effects were very different at different points in the neighbourhood and in the various positions of the receiver, but a law was soon found to apply to them. "The discovery and disentanglement of these extremely regular phenomena gave me peculiar pleasure," says Hertz. By an argument which was ingenious, though simple in its results and indisputably clear throughout, he established in each case how the electrical radiation must act at the different points in the neighbourhood of the oscillation, in order to produce the observed effect on the receiver, and he finally succeeded in giving a clear and intelligible account of the propagation of the radiation through space. Many remarkable phenomena then presented themselves, of which the older theories could offer no explanation. In the same year, 1888, he showed in his Paper on "The Forces of Electric Oscillations, treated according to Maxwell's Theory," that this theory gives exactly the same distribution of forces as his experiments had yielded, with all their peculiarities and apparent anomalies. Hertz set out in this Paper from the simplified form of Maxwell's theory which he had established in 1884.

Great discoveries now followed one after another, each representing a new triumph of Maxwell's theory, and, above all, of the newer views. The papers which were presented to the Berlin Academy between November 10, 1887, and December 13, 1888, mark a new era.

The Berlin prize problem now received a definite solution in the research "On Induction Phenomena produced by Electric Disturbances in Insulators." It was shown that "alternating conditions of electric stress or dielectric polarisation" produce electro-dynamic action and inductive effects, analogous to those set up in a conductor by a rising or decaying voltaic current. The older theories had for the most part disregarded the intervening medium, according to them the effect travelled directly across it; whereas Maxwell's theory had these electro-dynamic actions as one of its most important consequences. At the same time the old controversy concerning the action of "unclosed circuits" was set at rest.

Three months later appeared the Paper "On the Velocity of Propagation of Electro-dynamic Actions." In this research an experimental proof was given of the fact that electro-dynamic actions are propagated through space with finite velocity. For the velocity of electric waves in air a quantity of the same order as the velocity of light was obtained. For the velocity of propagation along stretched wires he found a value different from that in air; theory required them to be the same. In consequence of an error in calculation the velocity of waves in wires was found smaller than the velocity of light. But he here showed himself an unbiassed lover of truth. Although convinced of the truth of the theory he submitted his actual results, and confessed that he had here met with an unsolvable difficulty. Let us quote his own words on the subject, written four years later in the introduction to his book after he had explained the discrepancy:—"I have described these results in great detail because I wished to convince the reader that I was not merely endeavouring in this research to support a preconceived opinion by the most convenient and suitable interpretation of experiment. On the other hand, I have carried out the experiments, which in themselves were not easy, with the greatest possible care in the face of a preconceived opinion. And yet, with all my good fortune, I have had decided misfortune just in this experiment. For, instead of reaching the true result with small trouble, which a properly-arranged plan would probably have enabled me to do, I have apparently taken great pains, and fallen into error."

It was not discovered until later that the deviations from the theory were caused simply by the walls of the room, which reflected the electric waves impinging on them. Edouard Sarasin and De la Rive have finally shown that the velocity of propagation in wires has the same value as in air, each being that of light, by repeating Hertz's experiments on a large scale, and with every precaution, in the large machine shop of the Geneva Waterworks. The result is, therefore, quite decided for us now; but the disturbances which crept into Hertz's own experiments have given us a proof of his conscientiousness.

The account of the research "On Electro-dynamic Waves and Their Reflection" was published in the same year. Although Hertz had hitherto only succeeded in working with waves propagated along a wire, he now demonstrated the existence of similar waves in free space. Opposite the radiator a large screen of zinc plate, 8ft. square, was suspended on the wall; the electric waves emitted from the radiator were reflected from this plate, and on meeting the direct waves interference phenomena were produced, consisting of stationary waves with nodes and loops. When, therefore, Hertz moved the circle of wire which served as a receiver to and fro between the screen and the radiator the sparks in the receiver circuit disappeared at certain points, reappeared at other points, disappeared again, and so on. Thus there was found a periodically alternating effect corresponding to nodes and loops of electric radiation, showing clearly that in this case also the radiation was of an undulatory character, and the velocity of its propagation finite.

In the Paper "On the Propagation of Electric Waves along Wires" he shows that alternating electrical movements with frequencies as great as those under consideration (about a hundred million per second) are confined to the surface of the conductor along which they are propagated, and do not penetrate into its interior. This is a very important experimental confirmation of a theory of Poynting, founded upon the ideas of Faraday and Maxwell, concerning electric currents. According to this theory an electric current is a phenomenon which has its seat in the region outside the wire conveying it rather than in the interior of the wire. The magnetic effect of a current shows us that something goes on in this outside space which is very closely connected with the passage of the current. We are not to look for something flowing along the wire, but must rather consider that the energy enters the wire from without, and is thereupon converted into the special form of heat. It is thus not the copper core of a cable which conveys the energy from the sending to the receiving station, but the insulating layers surrounding the core; the terms "conductor" and "non-conductor" exactly change places. It is certainly true, as Hertz very pointedly remarks, that this apparent paradox only arises because we neglect to state what we mean by the term *conduction*. In reality the electric fluid of the older theories is abolished, in its stead have been introduced electric and magnetic forces existing independently in space, and advancing through it, carrying their energy with them, and for these the circumstances of conductivity are exactly the inverse of those for the hypothetical electric fluids.

In the course of his experiments Hertz had learned the method of producing, and working with, very short electric waves of 30cm. length. The oscillations corresponding to them could be collected by a concave cylindrical mirror and concentrated into a single beam of electric radiation. According to Maxwell's electro-magnetic theory of the phenomena of light such a beam must behave like a beam of light. That this is the case was shown by Hertz in his Paper "On Electric Radiation," the communication which has become the most popular one, and has created the greatest astonishment far and wide. The modest man says, in the introduction to his collected Papers, "These experiments succeeded each other quickly, and without any difficulty. The experiments with the cylindrical mirrors soon attracted notice, and they have been often repeated and verified. They have met with an approval quite beyond my expectation."

He showed how such electric radiation was propagated in straight lines like light, that it could not pass through metals, but was reflected by them; that, on the other hand, it was able to penetrate through wooden doors and stone walls; he also proved, by setting up metallic screens, that a space existed behind them in which no electric action could be detected, producing in this way electric shadows; and, by passing the rays through a wire grating, he succeeded in polarising them, just as light is polarised by passage through a Nicol prism. But the most striking experiment was that in which he directed the electric ray on a large pitch prism, weighing about 12cwt.; the ray was deviated, being refracted like a ray of light in a glass prism. Thus he gave to the whole its finishing touch, and the edifice was now completed.

In the communication which appeared three years later, and thus was dated from Bonn, "On the Mechanical Effects on Electric Waves in Wires," he demonstrated that not only does a wave of changes of electric state travel from the radiator through space with the velocity of light; but that along with it and inseparable from it there exists a magnetic wave, as theory requires.

In his last experimental work he finally returns to the phenomenon of discharge in gases, and shows, almost at the same time as E. Wiedemann and Ebert, that cathode rays can pass through thin films of metal, but are stopped by a dielectric film, no matter how thin it may be.

And now inexorable death set a limit to the further progress of the clever experimenter. We are indebted to him for two other Papers of a theoretical character, "On the Fundamental Equations of Electro-dynamics in Bodies at Rest and in Motion," which mark a great advance in the mathematical theory of electric and magnetic phenomena.

On his deathbed he completed a book, "On the Principles of Mechanics," to the early appearance of which the scientific world looks forward with intense interest.

Let us once more pass in review the chief results of his discoveries. He has freed us from the bondage of the theories of action-

Digitized by Google

at-a-distance, and concerning electrical and magnetic effects he has shown that they are propagated from particle to particle through space with finite velocity. This is a result of great and general, one might almost say philosophical, significance. The mysterious darkness which surrounded those secret distance-actions of former times has been cleared away; the dogma, honoured by science until now although unwillingly tolerated by reason, that something can act where it is not, has lost its application to the case of electric and magnetic actions. Further, the identity of the form of energy in the case of two powerful agents in nature has been conclusively established; light and electrical radiation are essentially the same, different manifestations of the same processes. The old elastic-solid theory of optics is thus resolved into an electromagnetic theory. The velocity of propagation of light is the same as that of electro-magnetic waves, and these obey the laws of optics; the scope of optics is enormously widened; to the ultra-violet, visible and infra-red rays with their wave-lengths which can be reckoned only in thousandths of a millimetre, are to be added waves many metres in length; the spectrum is infinitely extended, even if the rods and cones of our eyes do not respond to the new vibrations.

But in another direction we owe much to Hertz's investigations; we are, it appears to me, brought much nearer by them to a solution of the burning question, "What is electricity?" Hertz shows that there is no real electricity which can be regarded as a fluid as in the older theories; what we wished to explain by assuming it are conditions or states of a medium which, although hypothetical, manifests itself by its effects, "the ether," which permeates all matter. Led to this hypothesis, the phenomena of magnetism, electricity, and light apparently find at last a single explanation in a "Mechanics of the Ether." Whenever such an edifice is completed we shall be considerably nearer the possibility of finding a single explanation for the whole of nature. These are the results of the most recent discoveries, in which Hertz has played a most conspicuous part.

If we glance over the list of his contributions to science we ask in astonishment, "Is it possible that one man in the space of thirteen years could furnish such a wealth of new discoveries or open so many new avenues of research?" If the intense suffering of Hertz and his premature decease awaken our deepest sorrow, if the thought of what this mind might have explained makes us rail against the bitter fate that tore him from us, we may still say his was a short but happy and richly-rewarded life; the fame of our Hertz is secure, and will shine out during centuries of increasing intellectual development, whatever great deeds they may hide in their bosom; the influence of his discoveries will make itself felt as long as electro-magnetic waves continue to heat and illumine the earth.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July* 7, 1894.

Long-Distance Electric Roads.—Every now and then we hear of a new scheme for a long-distance electric railway, the latest project being for one between Washington and New York, whose promoters have applied for incorporation. None of these ambitious schemes have thus far gone beyond the promotion stage, unless we except the feeble attempts made by the Chicago-St. Louis line, whose prospectus dwelt in such glowing terms on the profits to be derived from transporting World's Fair visitors. In some cases the scheme for a long-distance line conceals another purpose, the real object being to secure franchises on better terms for short lines, which are represented as sections of a trunk line which is never built.

Purifying Water and Deodorizing Garbage.—Some of the members of our Tammany City Government seem to be greatly interested in a process for purifying the municipal water supply and deodorizing city garbage by electrical means. In the former case sea water through which an electric current has been passed is mixed with the regular water supply in homeopathic doses. We cannot learn how the process is to be applied to deodorize a garbage island that has become a pestilent nuisance; but this use has been proposed. As residents in the vicinity have applied for an injunction against further dumping there, though in the face of the promise of wonders when the electrical apparatus gets started, we fear that this latest political contribution to electrical science may not have an opportunity to demonstrate its merits in this respect.

Electro-Medical Science.—An employé of the Edison lamp works of Harrison, N.J., a few days ago was rendered unconscious by a shock from an electric current, in which state he remained for several days, notwithstanding the efforts of his physician. Finally, becoming convinced that the patient did not recover on account of being "full of electricity," the doctor, applying his electrical knowledge, connected one end of an insulated wire to a water pipe and the other end to a damp sponge, which was rubbed over the body of the injured man. After the first application an improvement was noticed, we learn, and in a short time the patient recovered consciousness and is now convalescent. All of which is hailed by the newspapers as a new curative principle for the treatment of electric shocks.

CORRESPONDENCE.

ENGINE REPAIRS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am glad to find from Mr. A. Lazenby's letter that the difficulties with closed type engines referred to by me in "Electric Motive Power" are now lessened in the improved types of the Willans engine; and I note that in condensing engines the temperature of the lubricant in the crank chamber does not often exceed 150°F.—Yours, &c.,

Suffolk House, Cannon-street, E.C., ALBION T. SNELL.
July 16, 1894.

LIGHTNING AND WOOD CASING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to your remarks on page 157 regarding the phenomenon of sparking resulting from Hertzian waves impinging upon separated main leads terminating in twin flexible conductors, I should like to point out that danger is also incurred where insulated conductors of opposite poles are placed in contact with each other at the points of crossing in wood casing. In some wiring I have inspected, the first fuse protecting these points was either the main, or was of such large diameter as to render it doubtful if it would act at the comparatively small current that would result from an arc so formed. If the fuse did not blow, and the arc was maintained, the wood casing in the immediate neighbourhood of the latter would probably become ignited.

If this occurred during the night, or at any time with no one at hand to switch off, or if no main switch were provided, it might be difficult to extinguish the fire or limit the damage.

As far as my experience goes, this faulty method of wiring appears to be on the increase; and it would be advisable for fire offices to insist on the separation of conductors until protected by a small fuse.—Yours, &c., CHAS. A. GAWTHORP.
July 6, 1894.

LARNE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your "Note" with reference to Larne in *The Electrician* of the 13th inst. is inaccurate, as there has been no new penalty clause added to our agreement. At the meeting you refer to, the engrossed copy of the agreement was before the Board for signature; but a Commissioner objected to its being completed on the ground that the penalty clause of the draft copy had been omitted in the fair copy, and it was then decided to consult the Board's solicitor, by whom the agreement had been prepared. The solicitor attended a special meeting on the 7th inst., and was able to show the doubting Commissioner that his suspicions were groundless, and that there was no necessity to make any alterations or additions to the agreement. It was then signed by the Chairman and two Commissioners. The discussion over this lighting agreement has been vigorously carried on since last October, and, apparently, there are some members of the Board who do not think the matter has received adequate attention even now. The arc lights referred to are of 1,200 c.p. each, and not of 1,700 c.p. as printed.—Yours, &c., ARCHER TURNER,
Electric Light Station, Larne. Manager and Engineer.

LEGAL INTELLIGENCE.

Latter v. Goolden.

This was an action before Mr. Justice Lawrance and a common jury, to recover damages for an alleged libel, and the defendants in answer pleaded privilege.

The case was of some importance in its relation to the question of giving "characters" to discharged employés The plaintiff was a lad in his seventeenth year. In June, 1891, he became a junior clerk in the service of Messrs. W. T. Goolden and Co., at Hanover-road, W.. at 8s. a week. He remained there until February, 1892, when Mr. Ravenshaw gave him a week's notice to leave. The father of the plaintiff was a workman employed in the Royal Mint, and he obtained a nomination for his son as a boy workman in that establishment, and when that situation was obtained the salary would be 15s. a week. The lad passed the preliminary examination, and the only question which remained was that of character, and there were communications between the Civil Service Commissioners and Messrs. Goolden and Co. upon this subject. The plaintiff did not obtain his appointment. It was known that there had been complaints at Messrs. Goolden's as to money having been filched from the pockets of coats that were hung up in the offices, and it was believed that what Messrs. Goolden wrote to the Commissioners connected the plaintiff in some way with this misconduct. Under these circumstances the father of the plaintiff wrote to Mr. Ravenshaw, who replied: "Your son is leaving my office as I have no further use for his services. We are getting rid of several boys, having more than we require, and your son not being an apprentice has been included in the list. I shall be glad to give your son a character for neatness and punctuality." The principal difficulty in the way of the plaintiff was to prove the publication of any libel.

A gentleman at the head of the department of the Civil Service Commissioners, who had to do with this matter, said that the documents which he was called upon to produce, and which was said to be libellous, contained a series of questions and answers in reference to character, and he declined to produce the document, it being confidential.

Mr. Justice LAWRANCE: That will not do.

WITNESS: And that it would be against the interest of the public service that it should be produced.

Mr. HALL, for the plaintiff, submitted that great injustice would be done to his client if that document were not ordered to be produced.

Mr. POWELL, for the defence: You have not yet heard our case.

Mr. Justice LAWRANCE regretted it, but he could not interfere as to the production of the document, for his hands were tied. The defendants were entitled to shield themselves behind this technicality, and there must be judgment for them.

Judgment was therefore given for the defendants, but the question of costs was reserved.

Coad v. Saunders.

In the City of London Court the plaintiff, Mr. T. Coad, electrical engineer, sued the defendant, Mr. Albert Saunders, solicitor, to recover £140, made up of £100 and £40. The first sum, it was alleged, the defendant had agreed to pay for the patent rights of an electrical apparatus invented by the plaintiff, and the £40 was claimed as the balance of an alleged loan. There was a counter-claim by the defendant for £152 in respect of money lent.

Having partly heard counsel for the plaintiff, the Recorder suggested that it was a case either for settlement or for reference to an arbitrator. A consultation then took place between the judge and counsel, and it was stated that the parties had agreed to a reference of all matters in dispute to the Registrar.

A formal verdict was returned for the plaintiff, subject to the reference.

Abell Electrical Engineering Company v. Pownal.

At the St. Helens County Court, before Judge Shand, on Wednesday, the plaintiff Company claimed £2. 17s. 6d. from Robert Pownall, alleged to be due for electrical apparatus supplied. It appeared that the defendant was the tenant of a farm at Sutton, and conceived the idea of working his fowl incubators by electricity. He consulted the manager of the Abell Electrical Company upon the matter, and at his request certain apparatus was supplied. The defendant afterwards alleged that the apparatus would not work, and refused to pay the account. He contended that the machine was a failure owing to bad workmanship, and said it had ruined 600 eggs, for which he paid a considerable sum.

As the plaintiff Company was in liquidation, and the proceedings were not instituted by the Official Liquidator, a nonsuit was entered.

Fire Pail Indicators.—It is stated that the superintendent of a large New England factory places all his fire pails on hooks which work on steel springs. The hook is strong enough to lift the pail when nearly empty, but a full pail forcibly depresses it. A metal point is so placed that when the spring in closing presses the point it closes a battery circuit and rings a bell in the office of the superintendent. He is thus constantly advised if the water in the buckets has evaporated, or if some one has borrowed the pails.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1894 Edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. This valuable book contains 1,000 closely-printed pages, and several new and useful features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," being four Lectures delivered before the Royal Institution in April-May, 1894, by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is in preparation, and will shortly be published.

"ELECTROMAGNETIC THEORY," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—This book, written by Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"INVENTIONS, RESEARCHES AND WRITINGS OF NIKOLA TESLA," by T. Commerford Martin, may be obtained from the Publisher of *The Electrician*, and a copy will be forwarded post free on receipt of 16s. 6d.

"HOW TO WIRE BUILDINGS."—Copies of this work, by Augustus Noll, will also be sent by the Publisher post free on receipt of 6s.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher

TENDERS INVITED.—The Corporation of Edinburgh invite tenders for work in connection with the electric lighting of the city under contracts 13, 14, 15, 16, and 17, which refer to the supply and erection of Willans engines, alternators, &c., switchboards, instruments, arc lamps, Ferranti rectifiers, and insulated concentric cables. Copies of the specifications can be obtained from the resident electrical engineer, City Chambers, Edinburgh, and all other information required will be supplied by Prof. A. B. W. Kennedy, consulting electrical engineer to the Corporation, 14, Old Queen-street, Westminster, S.W. Tenders have to be sent in to Mr. W. Skinner, W.S., Town Clerk, City Chambers, Edinburgh, not later than Monday, the 30th inst., for contract No. 15, and by Monday, August 6th, for contracts Nos. 13, 14, 16 and 17. Further particulars are given in our advertisement columns.

TENDERS ACCEPTED.—The Leith Dock Commission have accepted the tender of the Brush Company for the supply of electric light plant and fittings for a portion of the docks, and also the estimate of Messrs. R. Bruce and Son for the erection of an engine house, the latter for the sum of £640.

——— Tenders for wiring Wellington Court, Knightsbridge, have been received as follows:—

Roger Dawson (Limited), London (accepted)	£1,050	0
Spagnoletti and Crookes	1,090	0
Crompton and Co.	1,114	0
H. Joel and Co.	1,200	0
B. Verity and Son	1,261	0
Bolding and Co.	1,292	10
Vaughan and Brown	£1,380	0
Raynes, Smith and Co.	1,394	0
Planet Electrical Engineering Company	1,474	0
Bergthiel and Young	1,647	0
Julius Sax and Co.	1,668	0

——— The Bolton Corporation have accepted the tender of Messrs. Siemens Bros. and Co., for supplying and laying the necessary mains for the extensions in Knowlsey-street, as set out by the Corporation's Electrical Engineer, Mr. J. H. Ryder. It has been decided to substitute a powerful arc lamp for the gas lamps now lighting the Town Hall Square. The Electrical Engineer reported to the last meeting of the Corporation that applications had been received for about 2,000 8-c.p. lamps from the Corporation's mains.

——— The Stafford Town Council have accepted the tender of Mr. T. Smith, of Rodley, for an overhead traveller for the sum of £185. Dr. Hopkinson recommended the acceptance of the tender of Maignen's Filter Company for apparatus to be erected for softening the water before use in the steam boilers for the sum of £220. River water is to be used for this purpose at a saving of £350, as against the use of Corporation water.

REMOVAL NOTICES.—Mr. Charles Escaré, jun., owing to increase of business, has removed from Albert-place, Tottenham Court-road, to 128, Wardour-street, London, W.

——— Messrs. Siemens Bros. and Co.'s new address at Glasgow is 261, West George-street.

——— The Bournemouth and District Electric Supply Company (Limited) give notice of a change of address from Observer Chambers, Albert-road, Bournemouth, to Verulam-road, Yelveton-road, Bournemouth.

Digitized by Google

BOXES FOR ELECTRICAL GOODS.—Messrs. H. Nixdorff and Co., of 30, Maidstone-street, Hackney-road, N.E., who are wholesale packing and postal box manufacturers, have sent us samples of several sizes of strongly-made wooden boxes specially adapted for the carriage of light goods, such as electrical, mathematical, and optical instruments and instrument parts, incandescent lamps, small apparatus, lantern slides, &c. The boxes are especially handy for sending through the Parcel Post. They are made in any sizes, and those with an inside measurement of 3in. by 3in. by 2½in., made from ⅛in. timber, are supplied at 15s. per gross; 8½in. by 6½in. by 4in., with ¼in. timber, at 42s. per gross.

ELECTRIC ELEVATORS.—The following is an extract from a letter sent to a contemporary by Mr. Morgan I. M. Williams:—"The following figures of the cost of operation of an electrically-driven passenger elevator, erected for Mr. E. D. Stern, of Carlton House-terrace, at the commencement of the present year, may be of interest. The elevator is fitted with a 600lb. car, having a rise of 40ft., and is designed to work at the rate of 60ft. per minute, self-acting safety appliances of latest type being provided. It is operated from within by a simple regulating switch, and everything has, so far, given great satisfaction. The current is supplied from the mains of the local supply company, whose invoice shows cost of current for working during the last three months 9s. 2d., during which time the lift has been in regular use, the number of trips being probably about 400. The cost of an average journey amounted to from ¼d. to ½d., according to load."

EXPORTS OF TELEGRAPH WIRE AND APPARATUS, &c.—The present activity in the extension of the telegraphic system in various parts of the world is well shown by the official returns now available regarding the exports of telegraph wire and apparatus connected therewith from this country during last month. The exports have jumped in value from £90,077 in May last to no less than £341,646 last month, the latter figures comparing with £28,274 in June, 1893, and £24,177 in June, 1892. The returns of the exports during the first six months of the year are also now available, and these also must be considered satisfactory from every point of view. For the six months ending June last the exports have reached a total value of £883,741, as compared with only £479,195 in the first half of the year 1893, and £675,835 in the first six months of 1892.

ALLGEMEINE ELEKTRICITÄTS GESELLSCHAFT.—We have received an elaborately got-up and sumptuously-bound copy of the "Electric Lighting and Transmission of Power Manual, for Preparing Approximate Schemes and Estimates," which has recently been published by the above firm. The work is in English, and the phraseology is far superior to the average translation of German trade literature. It is furnished on the insides of the covers and on the facing pages with three large coloured maps, showing the chief towns, railways, &c., of the world. The frontispiece consists of a number of artistic coloured pictures of the offices, works and central stations belonging to the Company. The contents of the book comprises "A Synopsis of Electric Lighting Projects," and enters into mechanical and electrical design. Another section gives "Directions for Preparing Approximate Estimates," and comprises a number of neatly-arranged tables of the approximate costs of plant. The two tables of "Rates of Freight" should also prove useful. The remaining sections are devoted to descriptions of various electrical and mechanical machines, apparatus and fittings. The book is copiously and artistically illustrated.

"DUROL."—Messrs. W. Holz and Co. have just issued a circular giving particulars of "Durol," a hardening composition for steel. Accompanying the circular are instructions for using the material.

"MOUNTAIN, MOOR, AND LOCH."—We have received a copy of a useful publication issued by Sir Joseph Causton and Sons, entitled "Mountain, Moor, and Loch, illustrated by Pen and Pencil," giving descriptions of the West Highland Railway route. The book is issued with the object of reaching intending tourists through the beautiful district served by the West Highland Railway. The illustrations commence with a view of the Great Northern Station at King's Cross, and continue throughout to illustrate the route by rail and boat.

GERMAN CENTRAL STATIONS.—We have been shown a copy of an imposing volume prepared by the Helios Company, giving illustrations and descriptive particulars of the central stations erected by the Company at Cologne and Amsterdam. The work is by Mr. Carl Coerper, and has been translated from the German by Mr. Clarence P. Feldmann. As a specimen of the printer's art we have seen nothing better for years, and the lithographic engravings are on a large scale, and very clear and instructive. Several fine phototype views of the central station buildings are included in the work, to which we hope to make further reference at a later date. The agents for the Helios Company in this country are the International Electric Company, of Redcross-street, E.C.

ABERDEEN.—A proposal of the Gas and Electric Lighting Committee of the Town Council to increase the charge for electric current for public lighting from 2¼d. to 3¾d. per lamp per hour is to be discussed at the forthcoming meeting of the Council. This will bring the total cost of lighting the public lamps to about 4½d. per hour.——The presence of Prof. A. B. W. Kennedy in the neighbourhood has induced the Directors of the Northern Co-operative Company to have a careful examination and test made of the work which has been carried out in connection with the electric lighting of the Company's central premises. Prof. Kennedy congratulated the Company upon the enterprise they had shown in the matter of the electric light, and felt no doubt that the experience which had been gained by other public bodies would be realised in this case. The electric light had been proved to be a great advantage over gas lighting, especially in buildings where large numbers were employed, and where, especially during the winter months, a large amount of light was necessary.

AMBLESIDE.—The Local Board have received intimations from the Troutbeck Bridge Electric Lighting Company, and also from the Holloway Electricity Supply Company, that it is their intention to apply for a Provisional Order for lighting the district by electricity. The Local Board have withheld their consent to both applications.

ANNUAL DINNER.—The employés of Messrs. King, Mendham and Co., of Bristol, held their annual dinner at Weymouth on Saturday last.

ARBROATH.—The Northern Electric Light Supply Company having notified the Town Council of their intention to apply for a Provisional Order to light the district by electricity, the Provost stated that it would be necessary for the Council to apply for the order themselves in order to keep the lighting of the district in their own hands.

BEDFORD.—Correspondence has passed between the local authorities and the officials of the Bedford Electric Light Company, in reference to the obligations of the Urban Sanitary Authority in connection with their Electric Lighting Order, 1890. The concluding communication from the Company threatened to compel the authorities to lay down suitable and sufficient generating plant for the purpose of general supply in the various parts of the borough. A discussion arose on the subject of the letters, and it was decided that the Mayor should confer with the Secretary of the Company in the matter.

BOLTON.—In connection with the arrangements by which the Corporation supply electric light fittings on the hire purchase system, it has been decided to supply these fittings to consumers on the plan of one-eighth of their cost to be paid down and the remaining seven-eighths by equal quarterly instalments. Applications have at present been received for current equal to about 1,200 8-c.p. lamps.

BOURNEMOUTH.—The Bournemouth and District Electric Supply Company notify that arrangements have been concluded with the Brush Provincial Company, who have agreed to provide the necessary funds for extensions which the Directors of the Bournemouth Company have decided to carry out. Alterations have been made in the *personnel* of the directorate, which now consists of Mr. A. H. Sanderson, Dr. Hosker, and Mr. R. Percy Sellon. Mr. Sanderson is Chairman of the Board, and both he and Mr. Sellon are Directors of the Brush Provincial Company. It is pointed out that the Brush Provincial Company are owners of a large proportion of the Bournemouth Company's Ordinary shares, and that therefore the interests of the two concerns are identical.

BOWNESS.—The Local Authorities have received notice from the Troutbeck Bridge Electric Lighting Company that they intend applying to Parliament for powers to supply the district with electric current.

BRECHIN.—In reference to the intimations sent in by the Northern Electric Light Supply Company, of Aberdeen, and the Scottish House to House Electricity Company, of Glasgow, of their intention to apply for Provisional Orders for supplying Brechin with electric current, it has been decided by the Local Authority to leave the discussion of these matters with the Lighting Committee.

BROADSTAIRS (KENT).—The Broadstairs and St. Peter's Local Board have been notified by the Brush Provincial Company that they intend applying for a Provisional Order for power to supply electric energy for public or private purposes within the Local Board's district. It was decided after a short discussion that the Board should oppose the application.

BROMSGROVE.—Messrs. Hemming and Co. have applied for leave of the Local Board for laying down electric lighting plant, with the ultimate intention of applying to the Board of Trade for the necessary licence. The subject is to be further considered at the next meeting of the Board. Messrs. Hemming and Co., in their letter to the Board, state that in their belief it would be possible to supply electric current at the same price as is now charged for gas in the district.

Digitized by Google

BROUGHTY.—The Police Commissioners have been notified by the Northern Electric Supply Company of the latter's intention to apply for a Provisional Order for lighting the district by electricity. The Gas Committee have been instructed to consult an electrical engineer on the subject.

CARDIFF.—The work required for lighting Cardiff by electricity is nearly complete, only the erection of a few lamp-pillars remaining to be done. Nearly the whole of the machinery has been delivered, and it is expected that a start will be made on September 1st. Current is to be supplied at 6d. per unit; 48 arc lamps are, at the commencement, to be used for public lighting.

CHURCH LIGHTING.—St. James's Church, Taunton, has recently had its lighting arrangements remodelled, arc lamps having been replaced by clusters of glow lamps, of which 55 are in use. These are suspended from the crown of the arches in the nave and chancel. The lamps are of 32 c.p., and the electroliers are of wrought ironwork. The work has been carried out by Mr. F. M. Newton, the fittings being supplied by Messrs. Lea, Sons and Co. The current is taken from the Corporation mains.——West Hackney Church (London, N.E.), is to be lighted electrically when certain alterations to the interior of the church have been completed.

COATBRIDGE.—It has been decided to empower the Lighting Committee of the Town Council to spend £58 by way of experiment in lighting the streets with arc lamps, whereby it is expected a saving of from £25 to £30 will be effected.

COLLIERY LIGHTING.—The Alloa Coal Company have just lighted their Devon Colliery at Sauchie by electricity. Four 2,000-c.p. arcs light the pit-head; the engine-rooms, workshops, offices, &c., being lighted by 16 and 50-c.p. lamps. The whole of the pit-bottom, engine-rooms, stables, and main roads are lighted by incandescents. The Company have also introduced the electric light at their Bannockburn Colliery, both installations being carried out by Messrs. T. Laurie and Co., of Falkirk.——The Clay Cross Colliery Company are putting down a complete lighting plant for 200 16-c.p. incandescents to light their surface works and pit's bottom, the order having been placed with the Acme and Immisch Electric Works (Limited).

DENBIGH.—The gas works company, having refused an offer of 3s. 8d. per thousand cubic feet for the gas for lighting the public lamps, this scale having been suggested by the Lighting Committee of the Town Council, it was agreed to consider the best steps to be taken to secure an electric lighting installation for the town.

DEVONPORT.—At the last meeting of the Town Council the remarkable proposal was made that a contract should be entered into with the local Gas Company for lighting the public lamps by gas for seven years. It was pointed out by several members of the Council that the rapid progress made in electric lighting should cause the Council to pause before tying their hands for seven years to the Gas Company, especially in view of the fact that at the present meeting notices were received from several electric lighting companies of their intention to apply for Provisional Orders to light the district by electricity. It was decided to make the contract with the Gas Company determinable at the end of three, five, or seven years.

DUBLIN.—The Scottish Provident Institution, which has a large business in Dublin, has recently taken new premises at College-green. The handsome building, which is just completed, is lighted throughout by electricity, the work having been carried out by Messrs. Porte, Sykes and Co.

ECCLES.—The Electric Lighting Committee of the Town Council have been authorised to visit Whitehaven for the purpose of obtaining information regarding the proposed electric lighting scheme.

EDINBURGH.—The consideration of a proposal to extend the electric lighting area to an additional number of the principal thoroughfares in Edinburgh was, at the last meeting of the Town Council, deferred.

EXHIBITIONS.—It is intended to hold an International Exhibition of Arts, Industries, &c., at Bordeaux, in 1895, under the patronage of the French Government.

———— A committee has been formed in Paris with the object of organising an international electrical exhibition, to be opened on July 1, 1895, and to remain open to October 31st of that year. The exhibition is to be divided into two sections, one comprising generating apparatus, and the other to contain various electrical apparatus and machinery. The two sections, one of which will be situate on the Champs de Mars and the other on the Champs Elysées are to be connected by an electric railway.

———— An exhibition is to be held at Rouen in the year 1896 on the lines of the great exhibition held in the same city in 1884. Details are not yet supplied.

FORFAR.—The proposal of the Northern Electric Supply Company to obtain a Provisional Order for lighting Forfar is to be opposed by the Corporation.

GERMAN ENTERPRISE IN TURKEY.—The Acting British Consul-General at Constantinople refers, in a despatch to the Foreign Office, to a German association established at Constantinople during the past two or three years to actively push the sale of German machinery in all parts of Turkey. This association represents over 100 German firms, and sells none but German goods. It has premises in Galata, where specimens of various machinery can be seen, including engines, pumps, agricultural machinery, tools and implements, &c. An engineer is in charge, who explains the use and mechanism of the different machines to intending purchasers. The British Consul-General, in forwarding these particulars, invites British machinery makers to adopt the German method if they do not wish Turkish trade to pass entirely out of their hands.

GLASGOW CORPORATION ELECTRIC LIGHTING UNDERTAKING.—The Treasurer to the Glasgow Corporation Gas and Electric Lighting Committee recently reported that the electric lighting revenue for the year 1893-94, which ended on May 31st, amounted to £15,953. 19s. 7d., as compared with £6,189. 15s. 1d. for the year 1892-93, thus showing an increase for the past year amounting to £9,764. 4s. 6d. Some weeks since the Electrical Engineer to the Corporation (Mr. William Arnot) submitted plans showing what further plant could be accommodated within the Waterloo-street Station; and at a joint meeting of special sub-committees on extension of generating plant, distributing mains, and street lighting, recently held, it was resolved, after giving due consideration to the plans, to recommend that two additional steam engines and dynamos, with relative connections, &c., be put down within the station at an estimated cost of £6,000, that the engineer be instructed to prepare the necessary specification and, thereafter, to obtain and submit tenders for the execution of the work. After considering as to the additional boilers which it would be necessary to provide, the Sub-Committees agreed to delay further consideration of the matter until the Chairman (Councillor Burt) and the Engineer had obtained and submitted further information in regard thereto. On June 27th, at a meeting of the Electric Lighting Sub-Committee, the Engineer submitted the tenders which he had received for the two additional steam-engines and dynamos wanted for the Waterloo-street station, and the same having been opened and considered, it was agreed to recommend that the offer sent by Messrs. Siemens and Co. (Limited), be accepted, the amount of the tender being £4,885. On the same day the recommendation was approved of by the General Committee on Gas Supply and Electric Lighting, and it has since been passed by the Town Council.—It was decided some time back by the Glasgow and South-Western Railway to appoint a mechanical and electrical engineer for the St. Enoch's station installation, at a salary of £200 per annum. It has now been decided to defer the consideration of the matter, although we understand a number of applications have been received for the post.

GLOUCESTER.—With regard to the alterations now being effected in the Shire Hall, a question was asked at the last meeting of the County Council whether the electric light was to be adopted; but the architect, Mr. Medland, said it was doubtful if there was sufficient available power for the purpose.

GRANGE.—The Windermere and District Electric Supply Company have sent to the Local Board formal notice of their intention to apply for an electric lighting Provisional Order for this district.

GREENOCK.—At Tuesday's meeting of the Greenock Police Board attention was drawn to the communication from the Caledonian Electric Supply Company, of Edinburgh, notifying their intention of applying for a Provisional Order to supply electric current within the Greenock district. The Board instructed the Clerk to intimate to the Company that they would oppose the application.

HAMPSTEAD.—The Electric Lighting Committee of the Vestry have proposed a new scale of reductions in the charge for electric current supplied to private consumers as follows:—

Annual Bill. £	Proposed reduction.	No. of units metered.	Net cost per unit.
25	3 per cent.	1,000	5·82 pence
50	5 "	2,000	5·7 "
100	10 "	4,000	5·4 "
250	15 "	10,000	5·1 "
500 and over	20 "	20,000	4·8 "

A suggestion that the charge be 4d. per unit for current supplied during light load was referred back to the Electric Lighting Committee for reconsideration.

Digitized by Google

HANLEY.—The Local Government Board have sanctioned the borrowing of £10,000 for electric wiring and fittings for various Corporation properties.

IPSWICH.—At a recent meeting of the Suffolk Joint Committee a proposal to light the lunatic asylum by electricity was, under a misapprehension, rejected. At the meeting of the Committee on Monday last it was pointed out that instead of £1,700, only between £200 and £300 was to be spent on the lighting of the asylum, and the expenditure of this sum was approved.

IRELAND.—The Irish Electricity Supply Company are busy notifying the various townships of their intention to apply for Provisional Orders for lighting the various districts by electricity. The natural motive power possessed by the town of Ballena will, it is stated, decide the Company in commencing its operations in that town.

LEICESTER.—In an advertisement pointing out that cables are now being laid for the supply of electric current throughout the centre of the town and through many of the principal thoroughfares, Mr. Albert Colson, engineer and manager to the Corporation, informs intending consumers that the Lighting Committee of the Corporation are prepared to carry out and supply everything required in connection with house wiring and electric light fittings, for samples of which the Committee have provided show-rooms. ——The Midland Railway Company are extending their installation at the Leicester Station. For some time the extensive range of offices have been lighted by electricity, and extra plant has recently been laid down for lighting up the goods yard. The installation is complete, and the testing of the work has proved satisfactory.

LLANDUDNO.—The Llandudno Electric Supply Company have notified their intention of applying for a Provisional Order to light this district by electricity.

LONDON COUNTY COUNCIL.—The Public Control Committee have received a number of letters, resolutions, and petitions against the exorbitant price charged for gas by the Gas Light and Coke Company, who supply consumers north of the Thames. These petitions have been received from nearly all the local boards and vestries throughout London. The difference in the price of gas on the north and south sides of the Thames is no less than 8d. per thousand cubic feet. The Committee propose that applications should be made to the Board of Trade to hold an inquiry into the present management and working of the Gas Light and Coke Company, with a view of ascertaining whether there is any reason why the gas supply to consumers north of the Thames should be charged for at a higher rate than that supplied on the south side, and whether measures cannot be taken to secure uniformity of charge for all gas supplied within the London district. After some discussion the Committee's report was adopted.

LUTON.—The Bedford Electric Lighting Company have notified the Town Council of their intention to apply for a Provisional Order to supply electrical energy within the Council's district. Notice was given to the Company that the Council would oppose the application. It has been decided to oppose a similar application from the Municipal Electric Lighting Company.

MARGATE.—It seems probable that Margate will shortly be the only seaside resort unprovided with the electric light. It is singular that a town which has in the past done so much to cater for holiday traffic should be so backward in its lighting arrangements. The lighting of the esplanade at Hastings has had the effect of awakening public interest at Margate in the electric lighting question.

MESSINA (SICILY).—A report presented by the United States Consul at Messina to his Government states that much dissatisfaction is expressed by the citizens of Messina at the miserable light provided by the local gas company. There is here a great opportunity for any enterprising electric lighting company, as in Italy the people are willing to adopt the latest and best illuminant. The introduction of gas pipes is attended with much difficulty, owing to the fact that the buildings are almost entirely of stone. No such difficulty confronts the introduction of the electric light, as most of the buildings afford every facility for carrying electric wires through the various compartments. The Tramway Company have expressed a willingness to adopt electric traction on its lines running from Messina to Faro Point, a distance of 9 miles, and to Barcelona, a distance of 30 miles. The tramway system is at present operated by engines. Labour is cheap, land is cheap, and Cardiff coal can be bought at 16s. 6d. per ton. The business men of the city have promised earnest co-operation to make an installation of electric plant in Messina a success. The Consul advises personal attention to the matter on the part of companies disposed to enter into contracts with the local authorities, or to establish independent companies. He deprecates correspondence, as very few of the inhabitants understand English. He expects the gas interest to fight hard for its monopoly, but that success would ultimately attend the efforts of the electric lighting pioneer.

MORECAMBE.—With regard to the alleged nuisance caused by the Morecambe Electric Light and Power Company's station, at the last meeting of the Local Board it was announced that the medical officer of health would present his report in a few days, when the matter will be at once discussed by the Local Board.

MONTROSE.—The question of the introduction of the electric light into this town was again under consideration by the Police Commissioners last week, when it was proposed that application be made to the Board of Trade for a Provisional Order to enable the Corporation to supply electric current within the burgh. It was pointed out that already two companies had given notice of their willingness to supply the district, and that unless the Corporation took the matter in hand promptly the opportunity of keeping the electric lighting in the Corporation's hands would be lost. After some discussion the motion was carried.

MUSIC-HALL LIGHTING.—The Empire Music-hall at Aberdare has now been lighted by electricity, arc lamps being used for the auditorium, and incandescents for the footlights and stage.

PROPOSED BOARD OF TRADE DEPARTMENT FOR THE UNITED STATES.—It is believed that a movement is on foot in the United States to establish a Government Department corresponding to the Board of Trade Department in this country, and performing similar functions. It is to be termed the "Department of Commerce." It is pointed out that at present it does not appear to be the duty of any officer of the Government to procure and lay before the Congress the systematised statistics of the course and magnitude of the United States' internal commerce. Large sums of money are expended with the governing supervision of any department of State. This applies particularly to schemes of river and harbour improvement, and engineering schemes generally. It is intended to place matters of this character under the control of the new department.

PROVISIONAL ORDERS.—The Buxton Provisional Order has received the Royal assent.

RHONDDA VALLEY.—The electric light is becoming very extensively used in this district. Colliery owners are especially taking up the question of introducing the light into the mines. One of the latest additions is at the extensive collieries and works of the Ocean Company at Treorky, which have been partially lighted for some years, and have now been almost completely fitted throughout for the electric light. Ten years ago Messrs. Crompton and Co. supplied a large portion of the plant, and this is still at work. The dynamos are of the Bürgin type. At the Dare pit, which has also been supplied with plant by Messrs. Crompton and Co., extensions are in contemplation, and already about 300 16-c.p. incandescents are in use. At this pit the underground stables are also lighted electrically.

ROYAL COMMISSION ON LABOUR.—The fifth and final report of this Commission has just been issued in the form of two volumes. Evidence has been taken under eight headings:—(1) Conditions of Labour, (2) Associations and Organisations of Employers and Employed, (3) Relations between Employers and Employed, (4) Conciliation and Arbitration, (5) Limitation of Hours of Work by Legislation, (6) Irregularity of Employment, (7) Labour Department and Labour Statistics, and (8) the Employment of Women.

SHOREDITCH (LONDON, N.E.).—A report of the Electric Lighting Committee asks the Vestry to employ Messrs. Kincaid, Waller and Manville, as consulting engineers, to carry out the electric lighting and dust destructor scheme (the contractors for the dust destructor cells preparing their own plans and specifications upon requirements to be specified by Messrs. Kincaid, Waller and Manville), at a commission of 3 per cent. on the amount of the tender accepted on the original specification (no commission to be payable on extras), such commission to cover the preparation of plans and specifications (except as above stated), and the superintendence of the whole of the work as engineers to completion, and advising on the acceptance of all tenders. The contractors for the dust destructor must guarantee a specified amount of steam, but Messrs. Kincaid, Waller and Manville are to be responsible for the effective and successful execution of the whole of the work. A formal agreement is to be entered into embodying those terms. ——The Vestry have decided to apply to the London County Council for sanction to borrow £12,300 for the purchase of that portion of the Pitfield-street site which is to be used for the electric lighting station.

ST. BRIDE'S INSTITUTE.—This handsome building, now approaching completion in Bride-lane, Fleet-street, is to be lighted throughout by electricity. The institution is devoted to the printing arts, and is expected to prove a model technical educational institute. The electric lighting will be extended to the swimming bath, which is 75ft. long by 25ft. wide.

ST. HELENS.—A serious accident recently occurred at the Bold Colliery, St. Helens, where safety lamps are used. Gunpowder is not used at this mine, but roburite and carbonite charges are fired by an electric battery connected by a cable run through the workings. In connection with the accident, one of the men employed in the mine was charged last week with endangering the lives of the

Digitized by Google

men by incompetently working the electric battery. A "shot lighter" is employed, and, instead of waiting for this man to make the connection, the defendant attached the roburite charge to the electric wires, and when the second wire was attached and the circuit completed an explosion took place which might have resulted seriously, and which did, in fact, cause serious injury to the man now charged. The man, who had been rendered unfit for work for six weeks, was fined 14s. 6d.

St. Pancras (London).—The London County Council have agreed to lend the Vestry £14,300 for electric lighting purposes, at 3½ per cent. interest, payable quarterly, the principal being repaid by half-yearly instalments during 42 years ——At the meeting of the Vestry on Wednesday last it was moved by Mr. Churchwarden Thornley that Mr. C. H. F. Barrett, late chief clerk in the Department of General Business at the offices of the Vestry, should be promoted to the office of Vestry Clerk, rendered vacant by the death of Mr. T. Eccleston Gibb.

Tottenham.—The Generel Purposes Committee of the Local Board recommend the Board to decline to give their consent to the application of the Tottenham and Edmonton Electric Light and Power for o Provisional Order to light part of Tottenham by electricity, and further recommend that a Committee of the whole Board consider the advisability of the Board applying for a Provisional Order to themselves light the district.

Whitechapel (London, E.).—At the next meeting of the Streets Committee the expert's report on the electric lighting scheme is to be submitted and discussed.

Winchester.—A report is shortly to be presented to the Town Council in reference to the electric lighting scheme, regarding which the Electric Lighting Committee have been in communication with the Brush Company.

Windermere.—The Windermere District Electric Supply Company have notified the Local Board of their intention to apply for an electric lighting Provisional Order for supplying the district. The Board at its last sitting came to the conclusion that a company who would be prepared to safeguard the interests of the local authorities would probably receive the support of the Board in its application.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by Mr. J. C. Chapman, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

Note.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

June 28, 1894.

12,541. F. H. Nalder, C. W. S. Crawley, and A. Soames. London. Improved apparatus for intermittent measurements of alternating currents.

12,549. M. Immisch. London. Improvements in cables for telephonic and telegraphic purposes.

12,552. G. H. Nisbett. Liverpool. Improvements in protecting, and in fittings for connecting lead covered, or other armoured electric cables with naked or other conductors.

12,557. G. Trouvé. London. A system of luminous electric skipping rope. [Date applied for under Patents, &c., Act, 1883, Sec. 103, June 18, 1894, being date of application in France.]

12,566. A. E. Williamson. London. A dust-proof electrical switch.

12,605. W. A. Nikolajczuk. London. Improvements in, or in connection with, long distance telephones.*

June 29, 1894.

12,620. J. T. Niblett and M. Sutherland. London. Improvements in electric arc lamps.

12,650. B. M. Drake and J. M. Gorham. London. Improvements in storage battery plates.

June 30, 1894.

12,707. J. B. Verity. Birmingham. Improvements in or connected with electric lampholders, sockets, or connections.

12,748. W. Newbigging. London. Improvements in mounting electric and other lamps.

July 2, 1894.

12,767. W. H. Willatt. Hull. Improvements relating to electric incandescent lamps.

12,817. A. Zobel and F. Buchmüller. London. Improvements in electric incandescent lamps.

July 3, 1894.

12,861. E. Poppowitsch and H. Wüstenfeld. London. New or improved electrical fishing apparatus.*

12,870. C. Hamilton. Glasgow. Improvements in electric switches.

12,875. J. F. Kelly and W. Stanley. London. Improved alternating current meter and method of measuring alternating currents.*

12,877. H. H. Lake. London. Improvements relating to the operation and control of steam machinery or other mechanism by means of electricity, and in apparatus therefor. (J. D. Williamson, jun., United States.)*

July 4, 1894.

12,928. J. A. Edmondson. Leeds. Improvements in or in connection with the commutator brushes of dynamos.

12,946. S. Sealy-Allin and W. H. Wood. London. Improvements in arc electric lamps.

12,965. G. B. Blanchard and A. Ballance. London. An improved contrivance for automatically switching on and off electric currents suitable for many purposes.

12,972. S. Doubrava and J. Donát. Manchester. Improvements in electric arc lamps, and current regulators therefor.*

12,973. C. Hampel. Liverpool. An improved device for casting electric accumulator plates.

WATERLOO AND CITY RAILWAY COMPANY.—The report of the Directors of this Company, which, with the accounts, is to be submitted to the shareholders at the first half-yearly general meeting, to be held at the Waterloo Station, S.E., on Thursday, Aug. 9, at 2:30 p.m., is as follows: The prospectus which was issued by the Directors pursuant to the authority given to them by the shareholders at their meeting on Feb. 22 last resulted in applications for shares of the Company in excess of the number available for issue. An official quotation has been obtained from the Stock Exchange. The agreement between the Company and the London and South-Western Railway Company, which was sanctioned by the shareholders in February last, has received the approval of the Railway Commissioners, and the Board of Trade have given the necessary certificate for the payment of interest on capital during the construction of the railway, in accordance with the Company's Act of 1893. The contract for the construction of the railway from the Mansion House to Cross-street, Waterloo Station, has been let to responsible contractors, who commenced operations on June 18th last. The terminal stations in the City and at Waterloo will form the subject of separate contracts. The Directors recommend the adoption of the provisions of the Forged Transfers Acts of 1891 and 1892.

COMPANIES' MEETINGS AND REPORTS.

Electrical Power Storage Company (Limited).

The fifth ordinary general meeting of this Company was held at 4, Great Winchester-street, yesterday (Thursday). Mr. John Irving Courtenay (Chairman and Managing Director) presided.

The SECRETARY (Mr. J. W. Barnard) having read the notice convening the meeting, the report of the Directors was taken as read.

The CHAIRMAN said: I propose to offer but few observations, as the Directors' report and statement of accounts speak for themselves. We recommend a dividend of 5 per cent. and carry forward a substantial balance to next year. The reserve fund stands at £9,315. 7s. 1d., and it is satisfactory that we have been able to bring it up to that amount. I am glad to be in a position to state that the volume of business has very considerably increased, and that the actual cash turn-over is larger than it was last year, although the reduction in the list prices of 20 per cent. has been in operation during the whole of the year under review. In this business there is an increasing competition; but the E.P.S. batteries have held their own thoroughly well. The policy adopted by the Directors and Manager has been to continually improve the quality of the Company's manufactures, and the results show the E.P.S. batteries to be the most appreciated and reliable in the market, and that the sound commercial policy is to improve them in various details (though no startling new departure has been made), rather than to spend money and time in spasmodic efforts to obtain entirely new types or designs. One of the most important features to be noted is that the life of E.P.S. secondary batteries is steadily lengthening, so that in fact a sum equal to 5 per cent. per annum on the cost price is now amply sufficient for the maintenance in perfect working order of the batteries used under ordinary conditions. Those who remember the pessimistic views expressed only a few years ago as to what would be the safe annual percentage to cover maintenance will feel gratified at the practical illustration given by this Company of the correctness of the views of its representatives. I remember being told that it would never pay any Company to guarantee the maintenance of storage batteries at twice the figure now commonly adopted, but our manager has always contended that it could safely be done at about the present prices. Numerous fresh uses continue to be found for the employment of secondary batteries, and the number of our customers is larger than ever. We are not as yet able to point to a decided success in the application of E.P.S. batteries to traction; but we *must* make a success of this important branch of the industry, and I have full confidence that Mr. King will not fail in his efforts to this end, though undoubtedly the difficulties in the way of its development have been great. As stated in the report, unremitting attention has been given to the improvement of the batteries for traction purposes, and to appliances in connection therewith, and I hope that vehicles belonging to our friends, the Pioneer Electric Carriage Company (Limited), fitted with the latest type of E.P.S. traction battery, will ere long be seen in the streets of London. During the year various improvements have been made in the plant and in the arrangement of our works at Millwall, with the object of cheapening production; but I do not consider it advisable to indicate more fully the direction these improvements have taken. Our works have been to a certain extent remodelled, and several suggestions made by the Board of Trade for the greater comfort and health of our workmen have been carried out. The Company's Continental patents have been admirably protected by the Hagen Company and their legal and technical advisers, who have been most successful in upholding the patent rights. With these remarks I beg to move the adoption of the report and accounts.

Sir DANIEL COOPER, Bart., G.C.M.G.: I beg to support the motion—

"That the Directors' report and statement of accounts to May 31, 1894, be, and are hereby, approved and adopted, and that a dividend of 5 per cent. on the paid-up capital be declared payable forthwith."

After the remarks of the Chairman this resolution needs no observation from me.

The CHAIRMAN then put the resolution in the usual way, and it was carried unanimously. Continuing, he said: Having been associated with Mr. Fredk. Green for so many years, I may be allowed to propose his re-election, which is the next resolution.

Mr. J. W. BARCLAY seconded the motion, which was unanimously adopted. He afterwards proposed—

"That Messrs. James Meston and Co., 85, London-wall, E.C., be and are hereby re-elected auditors of the Company for the ensuing year for a fee of £60."

Knowing Messrs. Meston and Co. as I do, I am satisfied that they will not only protect the shareholders, but also the Directors in auditing the accounts.

Mr. FRANK KING seconded the motion, which was unanimously adopted.

In moving a vote of thanks to the Chairman, Mr. J. W. BARCLAY said that he took that opportunity of expressing the thanks of the shareholders to the Manager (Mr. Frank King) and the staff generally for the excellent results which the shareholders had had put before them, and which they consider due to the vigorous manner in which the business of the Company had been conducted.

The CHAIRMAN: In responding for the vote of thanks I have only to say that we all rejoice at the fact that we have had a very successful year,

Digitized by Google

There is no doubt that the past has been the best year we have ever had, and I trust that the same energy which Mr. King and his staff have brought to the work of the past year will bear fruit in the coming year. We do not fear competition, although we shall have plenty of it, but we are quite ready to meet it, and I believe we shall come through and win in the end.

Mr. KING said he would have much pleasure in conveying to the staff the fact of the shareholders' appreciation of their efforts during the past year.

The proceedings then terminated.

The following is the Directors' report :—

The net profit for the year is £4,936. 4s. 11d., which, with a balance of £158. 19s. 5d. from last year's accounts, amounts to £5,095. 4s. 4d., out of which the Directors recommend the payment of a dividend of 5 per cent. on the Ordinary share capital, which will absorb £4,101. 10s. 2d., leaving £993. 14s. 2d. to be carried forward. Provision has been made for the effective maintenance of buildings, plant, tools, &c., at a cost of £2,297. 6s. 2d. The sum of £3,323. 1s. 4d., the proceeds of sale of the Company's shares in the Société Française, together with a further sum of £4,000 out of the profit on the year's working, and £1,500 written off patents in 1892-3, have been applied to the formation of a reserve fund for diminution in value of assets, as shown in the balance-sheet. The Directors report the continued success of the Company's operations, and that there has been during the year a substantial increase of orders and of the uses to which batteries are being applied. The reduction in the selling price of the Company's manufactures has operated towards increasing the number of users, and so extending the goodwill of the business. Constant attention has been devoted to improving the conditions under which E.P.S. batteries are manufactured, and the Directors are sanguine of further success in this direction. The development of electric traction has received the unremitting attention of the manager. The Company and its licensees have been successful in patent litigation abroad.

Elmore's French Copper Depositing Company (Limited).

A general meeting of this Company was held yesterday at Winchester House, Old Broad-street, Mr. J. H. Duncan (the liquidator) presiding.

The CHAIRMAN stated that the specific object of the meeting was to appoint a Board for the reconstructed Company, but the shareholders would no doubt like to hear a statement as to what had been done with reference to the Company. Meetings were held in December last at which a scheme of distribution was approved, but the Long Vacation ensued, and the order of the Court was not drawn up until February 15th. The French Company had now got into thorough working order, and by the beginning of next month would be on an extended scale of working, having laid down considerably increased plant of an improved nature. The results of the first six months of the year had been seriously affected by competition, one large company having put down its price to so low a figure that this Company had not cared to follow them. However, he thought that this had now been brought to a point, and that in the remainder of the year they might expect things to go smoothly. In other respects things had been going extremely well in France, and the Company was becoming established on a good commercial basis. He suggested that in selecting Directors they should appoint a gentleman representing the Committee, one to represent the old administration, with the view of securing continuity of information, and a third who would represent the creditors.

A discussion followed, and, in the result,

On the motion of Mr. F. L. RAWSON, seconded by Sir JAMES MACKENZIE, Messrs. Duncan, Strettell, and Shurmer were appointed Directors ; but a further meeting was directed to be called to alter their appointments to that of trustees.

Major Jones (the late Chairman) was proposed as a Director, but he said he must decline to accept office on account of the state of his health.

Eastern Telegraph Company (Limited).

The forty-fourth half-yearly ordinary general meeting of the Eastern Telegraph Company (Limited) was held on Thursday, July 12, 1894, under the presidency of Sir John Pender, G.C.M.G., M.P.

The SECRETARY (Mr. George Draper) having read the notice convening the meeting, and the minutes of the last general meeting having been read and confirmed,

The CHAIRMAN said (the report having been taken as read): Before asking you to approve of the report I will, as usual, make a few remarks on it and also upon the working of the system in the last six months.

The gross revenue for the half-year under review amounted to £389,314 as against £372,853, or an increase of £16,461. Analysing the message receipts from various sources we find very little difference between the figures of last year, although there is an increase of about £4,000 in the trans-Indian traffic and a small increase in the Cape traffic. The new cable of the South African Company to Seychelles and Mauritius is working satisfactorily, and that Company is now receiving a subsidy from Her Majesty's Government at the rate of £28,000 per annum. The result so far as it has gone is fully up to our expectations, but the next time I have the pleasure of addressing you we shall have had a good 12 months' experience of the working of that system, and I think we shall be able to show that it is a link which will rather strengthen our position than in any way weaken it. The principal increase in the gross revenue is due to our having received £29,500 from our investment in the shares of the Eastern and South African Company, as against £17,700 in the corresponding period ; but, although there is an increase in the amount received this half-year, it is due to their having decided to pay the bonus at the end of the financial year, instead of half-yearly as formerly. The total amount received for the year ended March 31, 1894, is the same as that received in 1893. The total ordinary expenses for the half-year ended March 31, 1894, amounted to £102,219, as against £102,499, or a decrease of £280. The details are as follows: General expenses in London £8,912, as against £9,368, or a decrease of £456. The working expenses at stations amounted to £76,642, as against £79,926, or a decrease of £3,284. The principal decrease is in stationery and printing for stations. In the corresponding period there was included 15 months' supply of stationery for our stations, owing to our having altered the date of sending out supplies to a more convenient time in the year. For the purposes of comparison we shall in future show the proportions each half-year. Several other items also exhibit a substantial reduction, while others show an increase, the principal item under the latter head being in the salaries and wages of our staff at stations. This is due to the operation of the scheme to provide a regular scale of promotion to the superintendents and the other members of the staff. Travelling expenses also show an increase of £398. This is an item which must necessarily vary, and it depends in a great measure on the number of men on leave after serving the specified number of years abroad.

In reference to other items shown separately on the revenue account there is an increase in the following :—Maintenance ships reserve fund stands at £5,000 against £2,245, or an increase of £2,755. We have done very little work for foreign Governments and other telegraph companies this half-year, so that the full charge for depreciation on the ships is borne by ourselves. Speaking of the money which the ships have been earning, I may mention that this is rather a new feature in our system of working, and we now avail ourselves of it as much as we possibly can. As we have thoroughly-appointed ships, we cannot employ them better when we do not want them ourselves than in engaging them to other people who pay us for them. However, as I have said before, the best mode of employing our ships, so far as we ourselves are concerned, is to keep them lying idle, but fitted up and appointed and ready to sail when required. Full provision has been made for depreciation on our spare cable, and the currency balances at stations have been written down to their actual sterling value on March 31st last. The expenses attending repairs and renewals of cables amounted to £49,660, as against £32,533, or an increase of £17,127. Full details of the work done by our ships during the half-year will be found on Abstract C of the Report. It will be seen that they have been at work on our own cables, with the exception of a small repair for the Spanish Government, so that the credits derived from foreign Governments and other telegraph companies are small as compared with the same period of 1893. We have completely overhauled our steamship "Chiltern," and fitted her with new triple expansion engines and boilers, cable tank, &c., and have applied £18,000 in reduction of same out of the maintenance ships reserve fund, which, however, remains at the substantial figure of over £53,000. We expect from our experience in the case of other ships that we have similarly fitted that the saving in the consumption of coal will very soon compensate us for the large outlay we have incurred in putting in these new engines and boilers, &c. We have at present three ships laid up in London; but, as I have often told you before, and as I have just now repeated, we are better pleased when our ships are idle, unless, of course, they are at work for other people.

After providing the usual amounts for interest on debentures, debenture stock, and Preference shares, we are able to propose the usual final dividend of 1¼ per cent., and a bonus of 1¼ per cent., making, with the interim dividends already paid, a total distribution of 6¼ per cent. for the year ended March 31, 1894, and to carry the sum of £110,000 to the reserve fund, against £88,000 in the corresponding period of last year. We have also applied a further sum of £53,316 from reserve fund in reduction of the cost of Aden-Bombay No. 3 cable and other capital expenditure, so that our capital expenditure on account of cables, &c., remains, as it has done for many years, at the same figure. Meantime, we have strengthened our position by duplications and in other ways, and have thus greatly improved the value of our property in the market. The total amount applied out of the reserve fund now amounts to £1,345,644.

As will be seen from the balance-sheet, we have added to our capital investments £55,660 in the shares of the Europe and Azores Company. I have already explained to you that this Company was formed to lay a cable from Lisbon to the Azores, bringing those islands into direct telegraphic communication with our general system. In consideration of carrying out this work we have received an extension of our exclusive rights in Portugal, which in a great measure will recoup us for having made this investment. We did not anticipate that the Europe and Azores Company, so long as the cable only reached as far as the Azores, would give much return on the capital invested ; but there are other considerations in the concession which may shortly be fulfilled, and I have no doubt that when the matter is fully developed, the Eastern Company's position will be considerably improved by being associated with this latest development of submarine telegraphy.

Now, gentlemen, I have given you the hard facts. I am now going to make a few remarks generally on the position you occupy to-day. I think that when I say the report is favourable I am not stating anything but what you will receive as correct. The fact of our paying you your usual dividend, and carrying £110,000 to the reserve fund is no small indication of success, and I may remind you that this result has been obtained notwithstanding very bad times. I have had a great many years' experience of commercial life, and I can assure you that I have never known such a prolonged term of depression as has existed, and which still exists, not only

Digitized by Google

in London, but also throughout the world, I may say. There is, however, an elasticity in these things, and there is a boom coming. Our Colonies have got a considerable amount of "elbow room," and you may depend upon it that their energies will not long lie quiet. When they begin to display their energies again there will be a great response in London, because, after all, a great deal of the money that will then be required will have to come from London. When the revival does take place the times will be good for our submarine telegraph system.

Six months ago I stated that the Eastern and South African Company, in which we are the largest shareholders, had completed the Seychelles and Mauritius cable. That is a great work—a very important addition to our system—and one which, as I have just now intimated, is likely to add to our exchequer in the future. The Azores cable also is one which has attracted a good deal of attention. It is now in our hands. As I told you when we first entered into that transaction, we did so more with a view of securing advantages in the next ten years from the Portuguese Government for our Eastern system. Those advantages are most valuable, and will compensate us largely for the work we have done, even if nothing further comes from it; but I may say that when I next have the pleasure of addressing you, six months hence, if we are all spared again to meet here, I think I shall be able to show you that we have not been asleep on our Azores link, and to prove to your satisfaction that we are asssociated with a system which will make the Azores Company an important string to our bow. The amount of information given at the last two meetings leaves me comparatively little to say now. Six months ago I was able to tell you that the important work on which we had been engaged was completed, and to-day I have to announce that the Seychelles cable is working well, and that the Azores Company is doing its best. However, if we cannot get sufficient traffic with those islands we shall try and get it in some other way, and I think that we are in a fair way of doing some good in that quarter.

I cannot allow an opportunity of this kind to pass without remarking that the nations of the world—not only of Europe, but of the world—attach great importance to submarine telegraphy. You have all heard of the Conference that was held the other day at Ottawa, at which representatives from this country and from all the British colonies were present; and the principal question discussed was the Pacific cable. We must take credit for ourselves that we probably know more about cables than they do; and I am pleased to say they passed a resolution that soundings are to be taken, and that at the proper time this cable is to be laid. I think we may claim that after 25 years of successful and harmonious working, not only with the public but with most of the Governments of the world, that we may claim to have some say in an undertaking of such magnitude; and I may say further, that when it is required to be done, we can do it better and cheaper than any other existing company. I think that the experience we have got, and the statements we shall be able to make, will assure those statesmen who are taking a part in the project that the people to do the work are those who know the most about it. It is a bold thing for a man to do standing at a public meeting in London to say that he compliments the representatives of this country and of the colonies; but, still, I cannot help recognising that in discussing this question they have come to a very sound conclusion—that is, not to decide upon laying the cable until they know a great deal more about it.

Our relations with all Governments are of a most satisfactory kind, and I find that the longer we live the more respect we command, and the more useful we become to the nations of the world. It will be our policy to maintain such relations as will benefit the telegraphing public of the world, and at the same time not forgetting the interest of our own shareholders.

You are aware that next week we are going to celebrate the 25th anniversary of submarine telegraphy. The matter is so important that we could not allow this period to pass by without showing that we appreciate, as the world appreciates, the great work which has been done; and when we are able to say that after 25 years we occupy a position such as that which I have mentioned to you to-day, I think you will unite in congratulating ourselves on the great success which has attended our operations. I hope to have the pleasure of seeing on that occasion many who are present with us to-day, because we shall try, as far as possible, to make the occasion a proper recognition of our silver wedding, and we shall make it as general as possible. If there are any old shareholders present who have been overlooked they will receive an invitation if they will apply at the office. I have talked a little longer than I intended to, but I always think when I come here and we have our shareholders around us that we cannot spend an hour better than in giving them as much information as possible about the affairs of the Company in which they are all interested. With these remarks I now beg to move the following resolution:—

"*That the printed report and accounts of the Directors to March 31, 1894, submitted to this meeting, be and the same are hereby received and adopted. That a dividend on the Preference shares of the Company to June 30, 1894, at the rate of* 6 *per cent. per annum, be paid, less income-tax; and that, in accordance with the Directors' recommendation, a dividend be and is now declared of 2s. 6d. per share, with a bonus of 3s. per share, both free of income-tax, on the Ordinary shares of the Company, making with previous distributions by way of dividend on account, a total payment of 6½ per cent. on those shares for the year ended March 31, 1894.*"

The VICE-CHAIRMAN (the Most Hon. the Marquis of Tweeddale): I beg to second the motion.

The CHAIRMAN: Before I put the resolution to the meeting I shall be glad to answer any question which any gentleman may desire to put to me; but if no shareholder has anything to say I will ask you to approve of the resolution.

Mr. BAINES: I should like to make one or two remarks. I am very pleased at hearing such a satisfactory report this afternoon, but at the same time I must draw attention once more to the fact that the dividend for the Ordinary shareholders remains the same. The Company has earned a very large sum of money, but half-year after half-year we see £60,000, £80,000, £100,000, and £110,000 put aside for certain contingencies. Under those circumstances, after the duplication and triplication of so many cables, I do not think it is very difficult for this Company to pay 6½ per cent. I believe that in former times the prospect was held out of our receiving something very different. Circumstances have arisen to prevent that prospect from being realised, but at the same time I think that the time has arrived when the interests of the Ordinary shareholders should receive the serious consideration of the Directors. A dividend of 6½ per cent. is not a despicable thing—on the contrary, it is very respectable; but at the same time this Company, in my opinion, is capable of paying a still better dividend. I think if you pursue the course which you have shadowed forth in your remarks of economising in the management we shall also be benefited. In the conduct of a Company like this there is considerable expenditure, and I see that you have adopted a course of economy in connection with several items; but I think that that may be carried still further, and that by that means you may be able to pay an additional dividend of at least ½ per cent., if not 1 per cent. I referred just now to the large sums which are set apart. Those large sums have been earned by the original shareholders, and according to my view they ought to go to the shareholders in the shape of dividend. They are, however, devoted to other purposes. You have greatly strengthened the security of our property, and it has been in my mind several times whether the shareholders ought not to have in their pockets money which has been used for capital purposes. It is a risky proceeding to go on increasing your business to such a very large size, because you are liable to a great clamour being raised against you. You might give the shareholders shares *pro ratâ* according to their holdings, and thus obviate the clamour which might arise if you were to pay a very large dividend. I really think that the Directors should consider whether the interests of the Ordinary shareholders ought not to receive some larger attention than they do at present in the way of dividend.

The CHAIRMAN: I quite understand the views of Mr. Baines; but at the same time, if Mr. Baines understood matters as well as we do—if he were acquainted with them as well as we are—he would see that we are pursuing not only a prudent policy, but the very best policy in the shareholders' interests. We have not yet got a sufficiently large reserve fund, in my opinion, for our future requirements; but, while we are increasing it, and steadily increasing it, we are paying you 6½ per cent, which is equal to 8 per cent. 20 years ago. I say that 6½ now is quite equal to 8 per cent. at that time. I think that when the shareholders look at their dividend coming round steadily, as it does, and observe the market value of their shares, they recognise that the steady improvement which is going on in the value of their property is better for them, and this will be made more secure to them by the prudent way in which we are acting as regards the question of dividend. If we had acted in earlier days up to Mr. Baines' suggestion we should not be occupying the position we do to-day.

Mr. BAINES: I am speaking of the present time.

The CHAIRMAN: Men and companies nowadays are very much estimated according to their standing, and we shall be valued not only according to our position, but for the valuable work we are doing and providing for. If we can keep up a steady dividend such as we are now paying, and put by such sums as we are at present reserving, I think it is better for your interests. It is far better to put these sums to our reserve fund instead of dividing them, and then, perhaps, bringing down your dividend afterwards to 3 or 4 per cent. With regard to your idea about issuing shares, bear in mind that if you were to do so a dividend must be paid on such shares, and you would thus put an additional rope round the Company's neck.

Mr. BAINES: Oh, no.

The CHAIRMAN: Just bear in mind one thing. Legally, we could not do this to begin with; but what I want to impress upon you is that the course which we have pursued of duplicating and triplicating our cables, and not increasing our capital for such purposes, has been the most prudent and successful policy that we could have pursued in your interests. We intend to maintain that policy. We hope to continue the dividend we are paying now, and if our reserve fund should become very large and we saw that it was possible and advisable to give a little more to the shareholders, we should be only too glad to do so. That time, however, has not come yet. We have not such a reserve fund in hard cash at the present time as would justify us in distributing more. Besides, our experience has not yet told us what the life of a cable is. As long as we pay you this dividend and show you how we are handling the money I think that you ought to be satisfied. Years ago, Mr. Baines, we used to have these discussions, but I feel now, after 25 years' experience, you will tell us that our policy has been the right one, and that you were wrong in recommending us to do what you advised at that time (laughter). I do not want you to say outright that we have been cleverer than you; but the fact is that we were possessed of information which justified the course we have pursued, while you did not have that information, and could not give us sounder judgment than you did on these matters. I am quite sure that the bulk of the shareholders will support the policy of the Directors.

Mr. BAINES: In the course of your remarks you have assumed a position which I did not take up. In earlier years I did not advise an increase of dividend; it is only now that I have done so.

The CHAIRMAN: All that I can remember of those days is that we did not have a meeting but what there was not a great deal of fault-finding; but we were pursuing a straight policy. You come back, after an absence of 14 years, and come to these meetings, and instead of telling us that we have managed well and put the Company in a grand position, you come in a querulous way. You do not improve the value of your property in that manner. I am sure that in your quiet moments you must come to the

Digitized by Google

same conclusion as the rest of the shareholders—that we have benefitted you in a much greater degree than we should have done had we followed your advice.

Mr. BAINES: You are taking up a position which I never assumed. What you are saying may go down with some of the shareholders; but you really put me in a false position.

The CHAIRMAN: Well, I will sum up what you want. You want a bigger dividend, and you want to effect a change in our system by issuing a certain amount of bonus shares. We cannot do that. Look round and learn some little experience from the number of companies that have been what I may call playing with dividends and playing with their capital. We have not been doing so; we have been dealing with these companies in a practical form, and we have brought before you to-day practical results. That is the course which we have pursued and intend to pursue (hear, hear). At the same time I do not object to your having made your remarks, but we must now proceed with the business. Those who are in favour of the resolution will please to hold up their hands. To the contrary. Carried unanimously. I think that that concludes the business of the meeting.

Mr. JOHN NEWTON: I have much pleasure in rising to propose a vote of thanks to the Chairman and Directors for their services in the past half-year, and I may say for their services in the past 25 years. I was formerly associated with shareholders in adverse criticism of the Directors. I was at that time greatly disappointed that we did not get the 15 per cent. dividend, the prospect of which had been held out to us in the prospectus. But prospectuses are always deceptive. We all know in this case that the prospects held out to us were based on figures which were never realised. I am perfectly satisfied to be on the side of those who are to-day congratulating the Directors. At the former time to which I have referred our shares were standing in the market at about eight, whereas they are now quoted at nearly 16; and, whereas our dividends then were 5 per cent., they are now 6¼ per cent., which is equal to 8 per cent., if not more, in proportion. Gilt-edged securities used to pay 5 per cent. in those days, but they now only give 3 per cent. I think there is a great deal of cause for congratulation for all concerned in this Company, whether shareholders, Directors, or staff; and I do not think the shareholders will second Mr. Baines in his remarks about economy. I believe that those who know the subject thoroughly will be aware that the more you economise the greater your dividend will not become. The work must be done well, and well-paid services and the results we get are connected, depend upon it. I have great pleasure in proposing a vote of thanks to the Chairman and Directors for their services in the past half-year, and, as I have said, for the past 25 years.

Mr. BAINES: To show that I have no ill-feeling towards the Board I have great pleasure in seconding Mr. Newton's resolution, and in doing so I acknowledge the services which the Directors have rendered to the Company. The Company, however, is now in such a strong position that I think the time has arrived when the shareholders might expect to receive a little more in the way of dividend. I second the motion, and I have no doubt that it will be thoroughly supported.

Mr. DAWES put the motion to the meeting, and it was carried unanimously.

The CHAIRMAN: Gentlemen, Boards of Directors are human. We all like a little patting on the back when we have done our work well, and when that patting is done by gentlemen who formerly took a very active part in rubbing us down the wrong way the operation becomes still more pleasant (laughter). I thank Mr. Newton, who has been a very just critic, I may say, all these years, and when he comes forward so generously and acknowledges the work which has been done by us, my colleagues and myself are pleased, and thank him for the way in which he has dealt with us. I am quite sure, also, that if Mr. Baines will continue to honour us with his presence at these half-yearly meetings he will become as great an admirer of the Board's actions as Mr. Newton has become (laughter). In parting with Mr. Baines to-day I may say that it is a very natural wish that you should want an increased dividend, and he thinks that he sees some money in our hands that might be applied in that way; but, as I have said before, there are wheels within wheels, and if he had all the information that we possess affecting the policy we are pursuing, I rather think that he would endorse our views and be contented to leave things as they are. When the time comes and a change can be made which will be beneficial to you all, and the Board are justified in making it, you may rest assured that the thing will be done. I thank you again, gentlemen, for this renewed mark of your confidence.

The proceedings then terminated.

Anglo-American Telegraph Company (Limited).

The report of the Directors of this Company, to be presented at the ordinary general half-yearly meeting of the proprietors, to be held at the Cannon-street Hotel, E.C., on Friday, the 27th inst., at two o'clock, is as follows:—

The total receipts from January 1st to June 30th, including the balance of £844. 2s. 4d. brought forward, amounted to £135,390. 3s. 11d. This sum, however, is subject to revision, as the financial result of the judgment given in favour of this Company against the Paris and New York Telegraph Company cannot yet be estimated. The traffic receipts show a decrease of £16,791 as compared with the corresponding period of last year. The total expenses of the half-year, including the repair of cables, &c., amounted to £55,716. 15s. 6d., being a decrease of £4,465. 17s. 8d.

The Directors, under the powers conferred upon them by the Articles of Association, have, before declaring the net profits, set apart the sum of £12,000 to the renewal fund, leaving a balance of £67,673. 8s. 5d. One quarterly interim dividend of 9s. per cent. on the Ordinary stock, and of 18s. per cent. on the Preferred stock, was paid on May 1st, absorbing £31,500, and a second quarterly dividend of 10s. per cent. on the Ordinary stock, and £1 per cent. on the Preferred stock, amounting to £35,000, will be paid on August 1st, leaving a balance of £1,173. 8s. 5d. to be carried forward.

The Company's repairing ss. "Minia" has been employed during the past half-year by the Western Union Telegraph Company for the repair of cables belonging to that Company, the payments for which appear in the revenue account. She is at present engaged in the repair of the 1874 cable, broken on July 9th last year, 575 miles from Heart's Content. The new cable between Ireland and Newfoundland is in process of being laid.

The appeal in the proceedings between the Anglo Company and the Paris and New York Telegraph Company was heard in Paris in June, and judgment given on 10th inst. in favour of the Anglo Company, with costs to date. By this judgment the damages are to be assessed by experts, and are limited to the period between December 31, 1886, and May 21, 1891, the date on which the French Minister declared that the French Company's concession would be forfeited if it attempted to renew the contracts. The question of appeal is under consideration.

Direct United States Cable Company (Limited).

The following report is issued by the Directors of this Company for the six months ended June 30th, and will be presented at the thirty-fourth ordinary general meeting of the Company, to be held at Winchester House, Old Broad-street, E.C., on Tuesday, the 24th inst., at 2 o'clock:—

The half-year's revenue, after deducting out-payments, amounted to £34,843. 9s. 4d., as compared with £40,836. 17s. 4d. for the corresponding period of 1893, being a difference of £5,993. 8s. against the half-year under review, which is attributable to the prolonged commercial depression. The working and other expenses for the same period, including income-tax, amounted to £18,750. 3s., leaving a balance of £16,093. 6s. 4d. as the net profit of the half-year, making with £3,080. 10s. 10d. brought forward from the previous half-year a total of £19,173. 17s. 2d. For the corresponding period of 1893 the working expenses and other payments amounted to £18,898. 5s. 7d. Three quarterly interim dividends, amounting to £25,801. 15s., have been declared and paid during the financial year, and a final payment of 2s. per share is now proposed, making, with the three interim dividends, 2⅝ths for the year, being a total distribution of £31,872. 15s. After transferring £6,000 to the reserve fund account, which now stands at £281,551. 3s. 7d. the balance of £1,031. 17s. 2d. on the revenue account is proposed to be carried forward.

Sir John Pender, G.C.M.G., M.P., and James Pender, Esq., J.P., retire by rotation, and, being eligible, offer themselves for re-election as Directors, and Mr. John G. Griffiths, F.C.A., and Mr. John Sawyer, F.C.A., auditors, desire to offer their respective firms for election.

National Telephone Company (Limited).

The following is the report of the Directors of the Company for the 14 months ended June 30th last, to be presented to the shareholders at the fourteenth ordinary general meeting to be held at the Cannon-street Hotel, London, E.C., on Wednesday next, the 25th inst., at one o'clock:—

The income accrued in respect of the business of the 14 months amounts to £800,544. 15s. 8d., as compared with £583,590. 2s. 11d. for the preceding 12 months, being an increase of £216,954. 12s. 9d. The rentals carried forward for unexpired terms of running contracts amount to £345,358. 18s. 5d., as compared with £285,020. 7s. 8d. for the preceding year, or an increase of £60,338. 10s. 9d. The working expenses and other charges for the 14 months (excluding debenture and other interest) amount to £410,115. 3s. 10d., as compared with £311,644. 10s. 2d. for the preceding 12 months, being an increase of £98,470. 13s. 8d. The net result for the 14 months, after deducting the Post Office royalties, amounting to £73,945. 15s. 3d., is a profit balance of £316,483. 16s. 7d., as compared with a balance of £217,725. 2s. 11d for the preceding 12 months, being an increase of £98,758. 13s. 8d.

During the year the purchase of the Irish Telephone Company and some smaller undertakings has been completed, and the income arising from them has been brought into the accounts for the first time.

Out of the available balance of £262,311. 12s. 5d. shown by the net revenue account an interim dividend at the rate of 6 per cent. per annum on the First and Second Preference shares, and 5 per cent. per annum on the Third Preference and Ordinary shares, has already been paid. The Board will recommend a further payment at the rate of 6 per cent. per annum on the First and Second Preference shares, and 5 per cent. per annum on the Third Preference and Ordinary shares, making the dividend for the 14 months at the rate of 6 per cent. per annum on the First and Second Preference shares, and 5 per cent. per annum on the Third Preference and Ordinary shares. The Board also propose to transfer £63,429. 1s. to the reserve fund, so as to bring it up to £225,000, and to carry forward the balance of £1,765. 3s. 11d.

The negotiations with the Post Office in relation to the acquisition of the trunk lines of the Company have revealed many unforeseen difficulties of detail. These have occupied much time to solve in a manner satisfactory to both parties, but happily are now practically overcome, and the agreement itself is in such form as will enable the Postmaster-General to lay it on the table of the House of Commons in accordance with his promise to that effect.

Redemption of the Existing Debenture Debt of the Company.—The condition of the Money Market had for some time been such as to force upon the attention of the Board the question whether in the interest of the shareholders they must not avail themselves of the option reserved to the Company to redeem the £1,000,000 of Four and a-Half per Cent. Deben-

Digitized by Google

ture stock already issued. They came to the conclusion that they should do so, provided the terms upon which the success of a new issue could be practically secured would afford sufficient inducement. They ascertained that this could be effected by conversion into a Three and a-Half per Cent. Debenture stock, and accordingly the arrangement has been carried out upon the conditions of the prospectus advertised in the newspapers, and posted to the proprietors.

Four Directors retire, and being eligible offer themselves for re-election; viz., Mr. George Franklin, Mr. William Cuthbert Quilter, M.P., Mr. William Alexander Smith, and Mr. Alderman Joseph Thompson. The auditors, Messrs. Welton, Jones and Co. also offer themselves for re-election.

Various minor alterations in the Articles of Association are also to be submitted to the meeting for approval; these, if carried, will have to be confirmed by a special meeting to be subsequently called.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1894, pages 274-300, *&c., &c.*]

ECONOMIC ELECTRIC SPECIALTY COMPANY (LIMITED).—This Company was registered on July 11th, with a capital of £50,000, in £1 shares, to enter into and carry into effect an agreement made between Messrs. H. T. Middleton and Co., Edwin Blakey, and this Company, and to carry on the business of manufacturers of and dealers in electric, telegraphic, and scientific machines and instruments, electrical, mechanical, metallurgical, chemical and general engineers and manufacturers, and dealers in and suppliers of electrical engineering and other goods and apparatus. The subscribers (with one share each) are: James E. Hay, Charles Hoppe, Alfred H. F. Young, Sidney H. Nugent, Arthur T. Way, John Jackson, and William Lee.

J. C. AND J. S. ELLIS (LIMITED).—This Company was registered on July 13th, with a capital of £10,000, in £10 shares, to acquire the business carried on by J. C. and J. S. Ellis at Sheffield and London, and to carry on the business of general engineers and ironfounders.

HUGHES, SUTTON AND DIGBY (LIMITED).—This Company was registered on July 16th, with a capital of £5,000, in £1 shares, to acquire the business of engineers and contractors, lately carried on by George H. Hughes and Peter Gotto, at 8, Highgate-road, Kentish Town, London, N.W., and to carry on the business of hydraulic, electrical, mechanical and sanitary engineers, &c., to construct, lay down, establish, fix and carry out all necessary cables, wires, lines, accumulators, lamps and works for generating, accumulating and distributing electricity, and to carry on the business of electricians, suppliers of electricity for the purposes of light, heat, motive power and otherwise, and manufacturers of and dealers in all kinds of electrical apparatus and appliances. The first Directors are: George H. Hughes, Richard J. Sutton, and Thomas J. Digby.

JONES BROTHERS AND CO., BIRMINGHAM (LIMITED).—This Company was registered on July 11th, with a capital of £2,000, divided into 1,000 £7 per Cent. Cumulative Preference and 1,000 Ordinary shares of £1 each, to acquire the business of general brass founder carried on at Birmingham by Thomas W. W. Perry, and to carry on the business of general brass founders, manufacturers of electrical appliances, electrical engineers, manufacturers of and dealers in machinery, engines, tools, implements, utensils, and appliances, and founders, manufacturers, workers, and smelters of iron, tin, steel, copper, and other metals.

SPANISH TELEPHONE COMPANY (LIMITED).—This Company was registered on July 16th, with a capital of £16,000, in £10 shares, to acquire all the share capital, Ordinary and Preference, now issued of and in the Compañia Peninsular de Teléfonos, for the price of £32,000, to negotiate concessions, leases, or contracts for telephones, telegraphs, or other undertakings, and arrange for the construction and working of the same, and to carry on any business in connection therewith. The subscribers are:—Ernest Rüffer (500 shares), Henry Rüffer (500), Horace E. Walton (1), Walter H. Stevens (1), Alfred P. Garnett (1), Charles H. Garnett (1), and Frederick W. Rosey (1). The first Directors are: Ernest Rüffer, Henry Rüffer, and Francis R. Y. Radcliffe.

E. AND E. TAYLOR (LIMITED).—This Company was registered on July 14th, with a capital of £5,000, in £10 shares, to acquire the business of a hydraulic and electrical engineer, general ironfounder, &c., carried on by E. and E. Taylor, at Moorgate-street, London, E.C., and at the Brady-street Ironworks, London, E.

DALZIEL'S ATLANTIC TELEGRAM COMPANY (LIMITED).—The annual return of this Company, made up to May 14, 1894, has been filed. The nominal capital is £25,000 in £100 shares. Of these 228 have been taken up, and 150 issued as fully paid. The full amount has been called on one share, while calls amounting to £63 per share have been made on 77 shares, resulting in the payment of £4,719 and leaving £232 in arrears.

TELEGRAPH MANUFACTURING COMPANY (LIMITED).—The annual return of this Company, made up to June 18th, has been filed. Out of a nominal capital of £50,000, in £10 shares, 3,290 have been taken up, and of these 646 have been issued as fully paid. Upon the remaining 2,644 shares the full amounts have been called and paid.

THETFORD ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of this Company, made up to September 30, 1893, was only recently filed. 368 shares out of the nominal capital of £5,000, in £10 shares, have been taken up. Upon these shares the full amounts have been called, resulting in the receipt of £3,615, and leaving £65 as yet unpaid.

WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to June 12th, has been filed. The whole nominal capital of £300,000 in £10 shares has been taken up and fully paid.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to May 31st, was recently filed. Out of a nominal capital of £1,500,000, divided into 66,871 shares of £15 each and 66,258 shares of £7. 10s. each, 64,242 shares of £15 each, and all the latter class have been taken up, the full amount called, and £1,460,565 paid. A sum of £565 has been paid on 75 forfeited shares. Share warrants comprising 5 shares each to the total amount of £1,725 are outstanding, and comprising 1 share each to the value of £180 are also outstanding, while share warrants comprising 3 shares or £45 have been surrendered since the filing of the last summary.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to May 23rd, was recently filed. The nominal capital is £2,445,630, divided into 200,000 Ordinary, 34,563 First Preference, and 10,000 Second Preference shares, all of £10 each. 88,321 Ordinary, all the First Preference, and 4,669 of the Second Preference have been taken up, the full amount called, and £1,275,530 paid.

CITY NOTES.

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have, after placing the sum of £12,000 to the credit of the renewal fund, declared an interim dividend for the quarter ended June 30th of 10s. per cent. on the Ordinary stock and £1 per cent. on the Preferred stock, less income tax, payable on August 1st to the stockholders registered on July 10th.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The coupons on this Company's Five per Cent. Debentures, 1884 issue, due 31st inst., will be paid on and after that date at Parr's Banking Company and the Alliance Bank (Limited), Bartholomew-lane, London, E.C. Coupons must be left at the above bank three clear days for examination.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The accounts of this Company for the year ended June 30th show a balance, after providing for the Debenture interest and the full dividend on the Five per Cent. Preference Shares, sufficient to allow the payment of a dividend on the Consolidated Ordinary Stock at the rate of 1 per cent. per annum, carrying forward a balance of £1,335 to the new account. The dividend for the corresponding period last year was at the rate of ½ per cent. per annum, the balance carried forward being £898. It will be seen that an additional £450 is carried forward, and that the Company leaves the fractional dividends behind. The progress shown is very satisfactory, and augurs well for the new electric railway enterprise now in course of construction.——The traffic returns of this Company for the week ended July 15th were £882, as against £776 in the corresponding period of 1893, being an increase of £106. The total receipts for the half year amount to £1,761, as against £1,845 for the corresponding period of 1893, a decrease of £84.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The warrants for the interim dividend due on this Company's Preference shares, at the rate of 6 per cent. per annum for the six months ended June 30th last, have been posted.

INTERNATIONALE ELEKTRICITATS GESELLSCHAFT.—At the recent annual meeting, held in Vienna, a dividend of 6 per cent. was declared.

METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).—This Company have during the week invited applications for £150,000 Four and a-Half per Cent. First Mortgage Debentures (part of a total authorised issue of £250,000) at the price of £105 per £100 debenture. These debentures are redeemable at the option of the Company, on six months' notice after January 1, 1916, at £110 per debenture. The new stock is secured on the real estate of the Company, and is made a floating charge on the general undertaking. Holders of existing Five per Cent. Registered Debentures can exchange at par for the new stock, or will be paid off at the end of six months. The subscription list for the debenture issue opened and closed yesterday (Thursday).

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED) The transfer books of this Company will be closed from the 16th to the 24th inst. inclusive, preparatory to the payment of the interim dividend of 12s. per share.

VENEZUELA TELEPHONE AND ELECTRICAL APPLIANCES COMPANY (LIMITED).—Coupon No. 8 of the Five per Cent. First Mortgage Debentures of this Company, payment of which is due July 31st, will be paid from that date at the Consolidated Bank, Threadneedle-street, London, or at the banking house of Messrs. Westendorp and Co., Amsterdam.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended July 13th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £2,295.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the two weeks ending July 15th were £2,007, as compared with £1,893 for the corresponding period of last year. The receipts for March, estimated at £5,646, realised £5,656.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 845.—Vol. XXXIII. FRIDAY, JULY 27, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

The only noteworthy feature of the report of the Directors of the City and South London Railway Company is the announcement that the Company's engineer has been instructed "to make experiments with the view of substituting motors on the train itself in place of the present separate locomotive." We have often expressed the opinion that to use electric locomotives is to throw away one of the main engineering advantages of electric traction, and it is to be hoped that the saving in running expenses, and the increased accommodation the adoption of motor-cars will bring about will suffice to enable the concern to yield a more encouraging return to the ordinary shareholders than 1 per cent. Running expenses on the present system have now become stationary at 6·2d. per train mile, so that until the northern extension yields its anticipated profitable traffic a cautious substitution of motor cars for locomotives would appear to be the best available engineering means of improving the net income of the Company.

The Post Office authorities are now introducing telephones for telegraph purposes all over the country. These instruments have the great advantage that at small post offices every member of a household can use it; whereas with an A B C, or a single-needle instrument, skilled assistance is necessary. An attempt has been made to introduce them into the mountains of Wales, but a real Welsh grievance has at last been created. A whole district in Carnarvonshire has risen in revolt. The Rural Sanitary Authority of the place had agreed to a guarantee for a *telegraph*, not for a *telephone*. They were not going to have such a low, vulgar thing as a telephone! A telegraph they wanted, a telegraph they paid for, and a telegraph they would have, or the guarantee would be withdrawn. Welshmen, at any rate, evidently do not agree with the dictum of the late Mr. Justice Stephen that a telephone is a telegraph.

The letter from Dr. Koepsel, a translation of which we print with pleasure in our correspondence columns, clears up a point which his Paper had left doubtful in regard to his pretty and compact apparatus for determining the magnetic qualities of iron. It is clear that the demagnetising effect of the suspended coil is so small that the variations in its value due to differences of position are not sufficient to affect the reading. We think, however, that Dr. Koepsel is the only person who will suspect us of having confused the actual purpose of his compensating coil with that suggested by us as possibly necessary; for in the very next sentence to the one he quotes we state that the author *does not mention* this (*i.e.*, compensation for the swinging coil), and that it is quite possibly so small that it may be safely neglected. It is therefore unnecessary to reply to this portion of his letter; but as regards his conclusion, we cordially agree that a direct reading instrument is, *cæteris paribus*, preferable to the torsional form. We could wish that Dr. Koepsel had read our note more carefully, for another reason, for he would have been able to include in his letter the actual observations from a test bar by the ballistic method and those obtained with his instrument by shearing the curve. The curves in his Paper are on too small a scale to enable us to judge of the accuracy attained, and there still exists considerable doubt in our mind as to the possibility of determining the value of the magnetising force actually used on the test piece, the proportion of which to the total varies for every different value of the permeability. But Dr. Koepsel's Paper did not at all clearly indicate in what manner the value of H was arrived at, and his letter throws no further light on the subject.

At a meeting of an American engineering society the author of a Paper on "Municipal Electric Light Installation" recommended "the localisation of the power-house near a plentiful supply of water, in order that compound condensing engines might be used, and yet far enough from the business centre to escape excessive cost of real estate, while near enough to profit by transportation facilities." He might have added that the station should be near enough to the centre to supply the shops, and yet not so near as to make it difficult to supply the suburbs; and yet far enough away from everywhere to avoid risk of prosecution for smoke and vibration nuisances. The *desiderata* to be fulfilled by the ideal electric supply station are now-a-days at once so obvious and so unlikely to be realised to a greater extent than, say, 50 per cent., that consulting electrical engineers in particular and electrical engineers in general would do well to refrain from enumerating them—at least until they are called in by the municipality of Utopia.

According to a Paper recently read before the American Society of Civil Engineers by Mr. A. V. Abbott, Jun., telephone managers in the States have betaken themselves, like their exchange central-station *confrères* in this country, to plotting load diagrams. There have been several brilliant suggestions of

Digitized by Google

late of how best to increase the load-factor of our electric lighting stations by combining the business of lighting with this, that and the other trade; and if only a telephone exchange required a few thousand amperes at a few hundred volts, the most obvious combination would be to run telephones by day and glow lamps by night, since the load curves of the two businesses are to a large extent complementary. According to Mr. ABBOTT, a typical Chicago week-day telephone curve is a decidedly early riser, beginning to run up at 3 a.m., though it is not until 7 o'clock that the real business of the day commences, a first maximum being attained at about 10 a.m. The curve then falls till between 12 and 1, when it rises again to attain a second peak about 2 o'clock, after which the curve falls with varying rapidity until the early hours of the morning. Rather more business, we are told, is done on Monday than on any of the succeeding days, with the exception of Saturday. During Tuesday, Wednesday and Thursday the business decreases, reaching a minimum on Thursday. On Friday a slight increase occurs. The improvement in the Chicago service which has resulted from investigations of this description has been so marked that a regular system of counting now forms one of the features of the service, counts being made on the tenth of each month. The usual method of arriving at the rate of doing business is to supply the operator with a wooden peg, which at the commencement of the count she inserts in jack 0. As fast as calls are received she moves the wooden peg from hole to hole, counting calls something after the fashion of a cribbage board. At the end of each hour the superintendents note the position of the peg.

Errata.—In "Practical Wiring Chart" description, example (3) should read "·0897 × 40 = 3·588 H.P."; and example 5 (A) should read "horse-power lost per mile as 2·691," instead of the figures given last week.

Electric Lighthouses in France.—The lighthouse on the Island of Zen, in the Bay of Biscay, is to be fitted with an electric light flashing every five seconds and capable of being seen, in clear weather, within a radius of 52 miles.

Cable Interruptions and Repairs:—

	Date of Interruption.	Date of Repair.
Sierra Leone-Accra	July 2, 1894	July 25, 1894.
Para-Maranham	July 23, 1894.	—

Electric Lighting in Austria and Hungary.—The little village of Buccari, near Fiume, is now lighted by electricity, a "central station," driven by water power, having just been completed by the International Electrical Company of Vienna.

Institution of Mechanical Engineers.—The Summer Meeting of this Institution will be held in Manchester, and will commence on Tuesday next July 31st. The following are some of the papers that will be read: "Description of the new Electric Lighting Works, Manchester," by Dr. John Hopkinson, F.R.S.; "Electric Welding," by Mr. Benjamin Alfred Dobson.

Vacant Appointment.—The Council of the University College of North Wales, Bangor, invite applications for the post of assistant lecturer and demonstrator in physics at a salary of £120. The post is now vacant, and applications must be sent in by Monday, August 20th, to Mr. J. E. Lloyd, M.A., secretary and registrar, who will furnish all necessary particulars.

A Telephonic Test of Ability.—It is stated that a London merchant requires all applicants for clerkship to hold conversations over the telephone, and forms his opinion of their ability from their answers. His theory is that the day is rapidly approaching when three-fourths of the business will be transacted by telephone, and that a clerk who is careless or indifferent in replying to inquiries will drive customers away.

Epping Forest Electric Railway.—The London, Walthamstow, and Epping Forest Railway Bill came yesterday morning before a select committee of the House of Lords. The only opposition now comes from a landowner at Upper Clapton, through whose estate of forty acres it was intended to construct the line to connect the main line with the Midland Railway system at Tottenham.

The Latest "Most Powerful Light in the World."—The Lighthouse Board, says the New York correspondent of *The Times*, are arranging to place the most powerful light in the world on the Fire Island approach to Sandy Hook, being a Lepante lens with a light of *250 million candle-power* placed at an elevation of 168ft., revolving and flashing every 10 seconds, and visible to a vessel 140 miles from New York. The new light is to be established during the autumn.

The Kapp Dinner.—About 50 well-known electricians and professors met at dinner at the Whitehall Club last Monday to bid good-bye to Mr. Gisbert Kapp, and to present him with a *souvenir* marking the high estimation in which he stands in the eyes of the profession. The chair was taken by Mr. W. H. Preece, who made his usual felicitous speech in presenting Mr. Kapp with a silver salver, a non-magnetic watch, and an album of portraits of those present.

Electric Motors in the Chilian Navy.—Electricity has been used throughout the Chilian warship "Captain Prat" for manœuvring the heavy guns and ammunition hoists. The "Captain Prat," which is of 6,828 tons displacement, and carries 9.45in. and 4.72in. guns, has been built by the Forges et Chantiers de la Méditerranée. The motors used are of the Manchester type, and have been provided by MM. Savatier et Lagabbe, who have worked out all the details of the plant.

City and Guilds of London Institute.—The prospectus is issued for the session 1894-95, setting out particulars of the examination of the Central Technical College at South Kensington and of the Technical College at Finsbury. These particulars will be found set out in our advertisement columns, and all further particulars may be obtained at Exhibition-road, S.W., Leonard-street, City-road, E.C., or at the head offices of the City and Guilds of London Institute, Gresham College, Basinghall-street, E.C.

Telephone Rates in Switzerland.—The Swiss Government is at present engaged in deliberating upon a new Bill, the object of which is to considerably modify the law respecting the telephone service, especially as regards the annual subscription rates to urban exchanges. It is proposed to fix the annual subscription at 100 francs (£4) per annum for the first year, 80 francs (£3. 4s.) for the second year, and for the third and each succeeding year, 40 francs (about £1. 12s.) per annum. An additional charge of ½d. per conversation is, however, to be charged.

Mechanical Equivalent of Heat.—A correspondent of the *Engineer* states that the mechanical equivalent of the heat unit is habitually—but erroneously—taken at 772 foot-pounds, as given by Joule, and that the correct value is 789·2385 foot-pounds. As a matter of fact, Joule gave 772·55+, and the latest determinations give a value in the neighbourhood of 778, which is a convenient figure for general calculations. It is interesting to note that some writers, *e.g.*, Mr. Willans in his Papers read before the Institution of Civil Engineers, have used the approximate value, 770 foot-pounds, for J.

Painting Arc Lamp Globes.—The *Electrical Engineer* of New York says that the Louisville Board of Public Works has made an order requiring the Electric Light Company to refrain from painting or in any way obscuring electric light lamps paid for by the city. In some localities, at the request of property owners, the Electric Light Company has prevented the light from penetrating into private dwellings by painting spots on the globes. Hereafter this will not be permitted, and all of the globes will be permitted to give out a full light, no matter how much it may inconvenience individual property-owners.

Thunderstorms.—During a violent thunderstorm, last Thursday week, the upper parts of the north and west pinnacle of Whitwell Church were struck by lightning and "some old

Digitized by Google

rags" in the steeple were fired. A farmhouse near Chatham had a hole rent in the roof by lightning, one of the rooms being wrecked. A horse was killed and a man severely injured while standing underneath a tree which was struck by lightning at Bedale. During a thunderstorm at Hernhill the lightning struck a flock of poultry in an orchard, the fowls being found scattered all over the ground.

Patent Agents Bills.—The Select Committee on the Patent Agents Bills, of which body Mr. T. H. Bolton is Chairman, concluded their labours on Tuesday. The measure agreed to be reported to the House enables patent agents to constitute themselves a profession; provides for registration, discipline, and general control; and establishes a Statutory Committee to exercise supervision until the Chartered Institute of Patent Agents shall become sufficiently representative to take its place. The Committee have also embodied in the Bill some suggestions which have been made with a view to reforming the system of election to, and membership in, the Chartered Institute.

Electrical Engineering in Switzerland.—The electrical industry of Switzerland is becoming one of great importance, owing, in a large measure, to the enterprise of such firms as the Oerlikon Maschinenfabrik and Messrs. Brown, Boveri and Co. The following table, which shows the Swiss imports and exports of electric plant during the past two years, brings out the fact that not only are the imports decreasing but that the exports are rapidly increasing :—

	1893.	1892.
	Tons.	Tons.
Imports	44·6	86·4
Exports	1,045·9	750·6

Douglas and Laxey Electric Tramway.—The Isle of Man Tramways and Electric Power Company have completed their electric tramway along the coast between Douglas and Laxey, a distance of eight miles, and have opened out some of the finest cliff and marine scenery in the Isle of Man. On Saturday last the first trial car was run through. Dr. Hopkinson, who is a Director of the Company, was in charge of the trial, which was a complete success, the car running the whole distance without the slightest hitch. The line and system were found to be in working order. The Board of Trade inspection takes place to-day, the inspectors being Col. Rich and Major Cardew.

Junior Engineering Society.—The members of this society recently visited the electric and hydraulic installations of the Great Eastern Railway at and in the neighbourhood of Liverpool-street, by permission of the engineer, Mr. John Wilson, on whose behalf the district engineer, Mr. H. Wilmer, received the party and superintended the arrangements for their guidance over the extensive area included in the visit. The electric lighting station, situated in Norton Folgate, contains three 100-H.P. and four 200-H.P. compound vertical steam engines, each driving a dynamo. Steam is supplied by five Lancashire boilers, working at 140lb. pressure. The lights will consist of 212 arc lamps, and 4,773 16-c.p., 272 32-c.p., and 55 50-c.p. incandescents.

An Electric Police Launch.—According to the *Electrical Engineer* of New York an electric launch service is to be established as an auxiliary to the Philadelphia police service on the Delaware river. The General Electric Launch Company has filed a bid for the first boat, and other bids have been filed for the engine, charging dynamos, &c. The new boat will be what is called a "sneak boat," doing away with the rowboat of the Harbour Police, which is managed with much difficulty when the water is at all rough. This boat will enable the officers to approach river thieves and petty pirates silently, and is regarded by the police as a valuable recruit. It will also be availed of in connection with the river fire service.

A Submarine Cable Laid in a Water Pipe.—A submarine cable has recently been laid across the Narrows at Vancouver, British Columbia. The harbour about the Narrows is 3·16 miles long by 3 miles wide, whilst the Narrows is but 1,200 ft. wide by 60 ft. deep at its deepest portion. There is the same phenomenon of double tides for which Southampton Water is famous. The current runs through these Narrows at a speed which as a maximum reaches about 7 miles per hour, and the cables originally laid were quickly destroyed. There is, however, a water-pipe laid across this channel which has been successfully maintained, and it was finally decided to draw the cable through this pipe, which was accordingly done, and no further trouble has been experienced.

The North Sea and Baltic Canal.—The lighting scheme of the North Sea and Baltic Canal is a very comprehensive one, says *Engineering*, and the contract has been placed with the Helios Lighting Company of Cologne. At every 800ft. there will be placed incandescent lamps on both sides of the canal, on poles 12ft. high, the power of the lamps being 25 c.p., and of these lamps there will be altogether 884. In addition to this there will be 68 lamps for the lighting of the 13 ferries and the four bridges. The locks will each be lighted by 12 arc lamps, of which those at the entrance will have a special colour. Where the canal passes through lakes, which happens at two places for distances of, respectively, 4,000ft. and 19,000ft., there will be buoys with gas-oil lights. The electric machines will be located at Holtenau and Brunsbüttel, and the whole is to be ready by the spring of next year.

Condenser Discharge from a Man-of-War.—A curious fatality which occurred at the Norfolk (U.S.) Navy Yard on June 20th forcibly illustrates the necessity of guarding against atmospheric electricity in working about the great masses of steel that go to make up the modern warship. It appears that the steel cruiser "Raleigh" was in the wooden dry dock at the time, and a number of men were working on her hull, when a thunderstorm came up. The workmen sought shelter beneath the vessel, which rested on blocks in the centre of the dock. Suddenly, without warning, two of the men fell dead, and most of the others were knocked senseless, by an electrical discharge. The officers of the vessel, who were sitting about on deck, did not feel the shock; but it is alleged that all the compasses and similar instruments were affected, and the vessel has been permanently magnetised. The great ship had, in fact if the above account is correct, behaved like a huge condenser, and had discharged itself electrically through the men beneath it, who acted like discharging tongs.

The Physiological Aspect of Electric Shocks.—According to Prof. J. Kratter, of Graz, who has for some time been performing experiments on the effect of electrical shocks on animal life, death is most usually caused by sudden cessation of respiration and consequent suffocation; during the suffocation the heart continues in action. If the asphyxia lasts more than a certain time, about two minutes, the heart stops, this being a secondary phenomenon. Generally speaking, the animals used, cats, dogs, rabbits, and mice, were not easily killed by 1,600—2,000 volts alternating. The danger appears to lie in the nervous system, and to increase with the amount of brain development. Frequently death occurs by momentary stoppage of the movement of the heart; but a slow cessation of the heart's action, such as has been observed in cases of human death, was never observed. In no case was any anatomical alteration observable to which death might be attributed, but there are sometimes lesions, breaking of blood vessels; and the diagnosis is rendered certain by the peculiar burning at the position of contact, and by the escape of blood from the capillaries, which indicates the path taken by the current.

Self-Moving Road Vehicles in France.—The competition which has just taken place between some 46 mechanically-propelled road vehicles, on the roads between Paris and Nantes, Corbeil, and other places, will not prove of much direct interest to the electrical profession, as only one entry has been made for an electrically-driven vehicle. One half of the number of entries was taken up with petroleum motors which, in other respects than mere numbers, seem to hold the field, or rather the road, against every other type. The Daimler pattern of petroleum motor appeared to be the favourite. These vehicles are said to have a great sale to country doctors, who are enabled to do a round of from 40 to 50 miles a day by the aid of this novel means of locomotion. It is claimed that there is absolutely no smell of petroleum nor any objectionable odour whatever attending the use of the oil motor; but past experience of oil-driven vehicles, for which a similar claim has been advanced, leads us to regard this statement with considerable

Digitized by Google

incredulity. However, a small quantity of half-burnt petroleum oil gas discharged into a rural atmosphere would probably do little harm, and cause next to no annoyance.

The Telautograph.—By permission of the postal authorities the wires between St. Margaret's Bay and the General Post Office were last Sunday afternoon and evening used for the purpose of some experiments with the telautograph. Special instruments were fixed up at both ends, and as this was the first time that long-distance experiments in telautography have taken place in this country, they were watched with interest. The results were successful. Mr. Armytage Bakewell writes to *The Times* from Hampstead: "It has been stated that the recent experiments in the transmission of autographic messages by electricity between St. Margaret's Bay and London were the first which have been made in this country in long-distance telautography. Will you allow me to point out that this is a mistake, as more than forty years ago the copying electric telegraph, invented by the late Frederick Collier Bakewell, successfully transmitted autographic messages between Brighton and London. Invisible messages, which could be rendered legible by the recipient, were also transmitted by that system. Great interest was taken by the late Prince Consort in my father's invention, and the inventor had the honour of exhibiting the instruments and of explaining their mechanical and electrical details to his Royal Highness at Buckingham Palace. The copying electric telegraph was subsequently exhibited at the great Exhibition of 1851, and received the highest award, viz., the Council Medal."

Electric Radiation Experiments for Large Audiences—In a recent number of *Wiedemann's Annalen*, Dr. L. Zehnder, who has already published some interesting work on this subject, gives a few useful hints for making demonstration of Hertz's experiments more easily than heretofore. His first suggestion is that to avoid the evaporation and spray of the acid in accumulators, they should be covered with a layer 1 to 2mm. thick of liquid paraffin. Hertz's large parabolic reflectors, made of sheet metal, can be advantageously replaced by a wire reflector of about one-third of the size. For their manufacture the author has made three parabolic wooden formers, with a focal length of 12·5cm. These were placed parallel to one another and joined by distance pieces of 32cm. long; and at right angles to these formers were stretched wires about 1mm. thick and 1cm. apart. The secondary conductor lies along the focal line of the mirror so built up, which can, of course, be seen through. If the discharge tube be placed in this circuit, then if the primary sparks be shielded from sight the secondary sparks may be seen 25ft. away in a darkened room, if the distance between the focal lines of the primary and secondary mirrors is 2·75m. In order to make the reflectors just visible the author paints them with luminous paint. The small height of the mirror, about 4ft., enables the phenomena of refraction to be easily studied, an asphalt prism of three portions, each 22cm. high, suffices. The Deprez interruptor is found to be the best for the induction coil. The author proposes to replace his wire ribs by strips of metal about 5cm. wide.

Polyphase Mining Motors.—Messrs. Johnson and Phillips invited, last Friday, a few mining men and electrical engineers interested in mining, to inspect a polyphase plant about to be forwarded to the Sheba gold mine in South Africa. The plant is specially interesting from the construction of the dynamos, which are of the two-phase type, and have been designed by Mr. Kapp for the firm. Each practically forms two machines, and, hence, if one half is broken down from any cause, the other part can be used until arrangements have been made for carrying out the repairs. The construction is, in general appearance, similar to that of the Brown machines, the field magnets being of the same design. The armature coils, which of course are arranged around the outer and stationary part of the machine, are not symmetrically placed with reference to each other, but the top half of the poles are set with an angular lead of 90 deg. with respect to the remaining poles. The result is that there are two distinct currents, the one in the upper coils being in quadrature to that in the lower. The motors were built by Messrs. C. E. L. Brown and Boveri. The stationary part is supplied with the two-phase current; and the revolving part, which forms the field magnet, is wound with three coils connected to three rings and a variable resistance. The torque can thus be controlled within wide limits. At starting the torque is comparable to that of a continuous current machine of the same output. This was roughly demonstrated by Mr. Albion T. Snell, who has given special attention to this class of motor. We shall refer to these machines at an early date. At the present we wish to point out that the doubt about the starting torque of polyphase motors no longer exists.

Magnetic Action of Hertzian Waves.—A recent number of the *Comptes Rendus* contains a note, by M. Birkeland, on some recent work done in the late Prof. Hertz's laboratory. It is well known that Hertzian waves when they travel along an iron wire magnetise it transversely, although they only penetrate a very short distance below the surface of the wire. This being so, it was an interesting problem to investigate whether it would be possible to observe in such a wire nodes and loops in the magnetisation. Experimenting in this direction, M. Birkeland was led to a negative result, which he attributed to the electrical conductivity of the wire, and hence he was led to experiment, not on cylinders of iron, but on mixtures of finely divided iron and paraffin. He uses a square resonator, having each side 60cm. long, the opposite side to the spark micrometer being formed into a coil of twelve turns, well insulated from each other. If a cylinder of soft iron is introduced into this coil, the spark length is not changed; a fact which previous experimenters have shown to be due to the screening effect of the induced currents in the superficial layer of the mass of metal. When, however, a cylinder of the mixture of iron and paraffin is introduced into the coil, the spark length may be reduced from 9mm. to 0·05mm., or to $\frac{1}{180}$th of its original value. The effects observed increase as the electrical conductivity of the cylinders diminish, so that the magnetic action of the iron becomes less masked by the conductivity effects. This is well shown by surrounding the cylinder with tin-foil, when the spark regains its original length. When a hollow cylinder of the mixture of iron and paraffin is introduced into the coil, the spark length is much shortened; but the effect is much enhanced when the hollow cylinder is filled by a solid rod. Thus the author finds that the magnetic action is felt through a thickness of 5mm. when the mixture contains 25 per cent. of iron, and through 7mm. when it contains 10 per cent. of iron.

Loss of Fuel with Banked Fires.—One of the things generally overlooked in the management of a factory steam plant is the treatment which the plant receives at night when the fires are banked. In some places, says an engineering contemporary, the dampers are left wide open, and a current of air is allowed to draw in over the fires through the tubes of the boilers, and thence to the chimney. In other cases the dampers are closed, but they leak to such an extent that a considerable quantity of air finds its way through the boiler. It is needless to say that the effect is to cool the boilers, but the extent to which this operates even where the leakage of air is comparatively slight, is seldom appreciated. An instance may be noted which shows that the matter is of considerable importance to those who are seeking the highest fuel economy. The case was one where the fires were banked at 6 p.m. and no steam was used from the plant at night save that which was condensed in the main steam pipes, and this was returned to the boiler by means of an automatic pump. The boilers were of the water-tube type, and they were fitted with hand dampers in addition to a main damper in the flue. The common practice was to shut the main damper and leave the firedoors open with a pressure of 100lb. at the time of banking. The main damper was not perfectly tight, and there was sufficient air drawn in to cool the boilers, so that when the fires were opened at six the next morning the steam pressure had fallen to 10lb. Subsequently the practice was changed by closing the hand dampers as well as the main damper, and closing also the fire and ash doors, no other condition in the operation of the plant being changed. The result was that instead of having a pressure of 10lb. at the time of pulling down the fires there was a pressure of 40lb., and the bank of coal which was previously more or less consumed was in apparently the same condition as when the banked fire was first covered.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(Continued from page 295.)

Furnaces and Boilers.

"Galloway" Boiler.—There are three essential particulars in which the "Galloway" boiler, manufactured by Messrs. Galloways, of Manchester, departs from the pure type of Lancashire boiler. These are: The use of a breeches flue for the internal flue, the adherence to the old mode of external setting by carrying the furnace gases through the side flues previously to through the bottom flue, and the introduction of "Galloway" cross water tubes. The breeches flue is shown at the bottom of Fig. 19, with the back end in the foreground. It consists of two furnace flues, of circular form, each containing a separate grate and set of fireplace fittings, uniting into one common kidney-shaped flue behind the bridge. This common flue is traversed by a number of cross water tubes, and is provided along both sides with deflecting pockets or indentations. It is claimed that the union of the two lots of furnace gases behind the bridge leads to higher economy, for, by alternately firing the two grates, the excess of air in the thin fire will help to burn up the incompletely burned gases carried over from the thick fire.

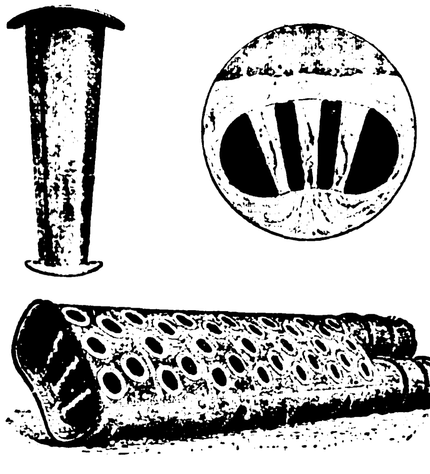

Fig. 19.

"Galloway" Tube.—The "Galloway" cross tube serves a number of useful purposes in this boiler. The shape of the kidney-shaped flue and its extreme width cause it to be subjected to great collapsing force when it is under steam pressure, and render some form of stiffening necessary. The cross tubes, primarily designed to provide this necessary stiffness, also fulfil the following useful ends:—(1) They promote rapid circulation of the water. (2) They increase the effective heating surface, and that in a part of the boiler where the gases are almost at their highest temperature. (3) They act as bafflers to the furnace gases, producing admixture of the hotter and colder portions of these gases. A single tube is shown in Fig. 19, which also illustrates the circulation given by these tubes to the water. It consists of a truncated cone, provided with two flanges for riveting the flue. The smaller of these flanges is riveted on the furnace side, and the larger on the water side of the internal flue. The introduction of the "Galloway" tube into Lancashire and other boilers is a very useful departure from the pure types. The economy of fuel caused by the introduction of these tubes is estimated at from 10 to 25 per cent. A "Galloway" boiler having a shell 28ft. in length and 7ft. in diameter will give a normal evaporation of 6,000lb. of water per hour, when supplied with good coal. The usual allowance in large boilers of this type is 3 sq. ft. of heating surface per indicated horse-power, and 46 to 48 sq. ft. of heating surface per square foot of grate.

Locomotive Boiler.—It can scarcely be said that there is such a thing as standard practice in locomotive boilers, since the proportions of the various parts must depend on the class of work which the boiler has to perform, and on the class of fuel to be used. This type of boiler is used for an immense variety of purposes, from railway engine and torpedo boat driving to agricultural machinery working; and it may be designed to burn all classes of fuel. Take, as an example, a locomotive boiler manufactured by Messrs. Robey and Co. The grate, which is almost square, has a total area of 13.2 sq. feet. With high draughts a considerable thickness of fuel may be burned on the grate, but under ordinary conditions the combustion would not exceed from 25lb. to 30lb. of coal per square foot per hour. From the upper part of the inner fire-box the hot gases pass along the fire tubes to the smoke-box, which is situated just below the uptake or funnel. There are 62 of these tubes, each of 2¾in. diameter. The area of heating surface supplied by these tubes is 424 sq. feet; and this, together with 69 sq. ft. supplied by the inside fire-box, makes a total effective heating surface of 493 sq. ft. A negligible heating surface is afforded by the smoke-box tube-plate. The ratio of the heating surface to the grate area is therefore about 37·4. The shell and other parts of this boiler are designed to stand a working pressure of 140lb. per square inch. Supplied with hot feed, and burning good coal, this boiler should be capable of evaporating about 2,000lb. of feed water per hour. It may therefore be rated at about 100 actual H.P., for ordinary rates of working, though on occasion the boiler might be forced to develop steam at a higher rate, and thus to drive a higher horse-power of engine.

"Economic" Boiler.—Messrs. Davey, Paxman and Co. manufacture, under their patents, a type of boiler called the "Economic" boiler, which has found a prominent place among electric power station steam generators. Strictly speaking, the "Economic" boiler is not a distinct type, but a combination of the Lancashire and marine patterns. It consists of a horizontal, cylindrical shell, terminating at each end in a flat end-plate, and traversed by two cylindrical furnace flues, each with a separate fireplace, as in the Lancashire boiler. The upper portions of the end-plates form tube-plates for a large number of longitudinal fire tubes, and at the front end these tubes terminate in a smoke chamber. The boiler is set in brickwork in the following manner: The back end terminates in a deflecting chamber, lined with firebricks, by which the furnace gases are passed from the under flues to the upper fire tubes. This combustion chamber, as it may be called, becomes almost white hot when the furnaces are in an active state; and the regenerative effect of its heat on the gases ensures the perfect combustion of any unburnt gases which may pass through the chamber. Passing from this chamber forward along the fire tubes, the gases reach the smoke boxes at the front end, and here they pass in two portions to a couple of external flues, which are built around the lower sides and bottom of the shell, with a dividing partition and foundation for the shell directly below the centre of the shell. The course of the gases is now backward towards the economiser, if one be used, and the chimney. By this arrangement of flues the hot gases are made to traverse the inside of the shell twice and the outside of the shell once; thus giving a much greater proportion of internal heating surface, and less surface of external brickwork for the absorption and loss of heat. Instead of having external flues, it is possible to arrange that the hot gases after leaving the smoke-box shall pass to a down-take and away to the chimney; but this arrangement reduces either the efficiency or the steaming performance of the boiler, owing to the reduction of heating surface. The arrangement is convenient, however, where it is desired to mount the boiler on iron saddles instead of in brickwork. This boiler gives the best results, assuming ordinary steam coal to be used, if worked with a draught not less than ⅝in., and it is found that with this draught about 5lb. of water can be evaporated per square foot of heating surface per hour.

The following comparison between the proportions of an

Floor space	432 sq. ft.	195 sq. ft.

"Babcock-Wilcox" Boiler.—The water-tube boilers manufactured by Messrs. Babcock and Wilcox have hitherto led the way as steam generators for electric power stations, both in Europe and America. It is important, therefore, to consider the principal features and merits of this type of boiler. The particular pattern of Babcock-Wilcox boiler which is so well known in European electric power stations differs in some respects from the two or three varieties which are common in America. The boiler is composed of a large number of water tubes, placed in an inclined position, and connected at each end by means of vertical passages with a steam and water drum, placed horizontally over the range of tubes. The upper or front end of the tubes is placed immediately over the grate and forms the crown of the combustion chamber; while the rear end of the tubes is connected to a cylindrical mud-drum, placed transversely to the length of the boiler. The water-tubes are set on a zig-zag pitch—*i.e.*, they are "staggered"—so that the tubes in each row lie just above the spaces between the tubes in the row immediately below. As the furnace gases pass between the tubes this arrangement provides for efficient circulation and contact with the heating surfaces. The whole of the tubes and half the steam drum are filled with water, and the direction of the water circulation is down the vertical connections at the back, forward along the tubes, upward at the front along the vertical connections, and backward along the steam drum. A mixture of steam and water rises through the front end connections, or "headers," and the steam is separated from the water in the drum. Steam is usually collected at the rear end of the drum, to facilitate this separation of steam from the water. The boiler is set in brickwork, built into a steel or wrought iron girder framing; and the setting is so arranged that the entire load of the boiler is imposed on the girders alone, and not on the brickwork. By this arrangement any stress due to unequal expansions of the boiler parts and the brick setting is avoided, and the boiler runs less risk of injury from rapidly getting up steam than would otherwise occur. The brick setting is lined on the inner faces with firebricks. The bridge, immediately behind the grate, and the hanging leaf, which is placed between the middle and rear sections of the tubes, are also of firebrick. These serve to deflect the hot gases across the tubes, the gases traversing the tube stack three times in this pattern of boiler.

The majority of the Babcock-Wilcox boilers which now exist at electric power stations in this country are built of lap-welded wrought-iron tubes, with steam drums of the same material or of wrought steel, cast or wrought-iron mud-drums, and forged or cast-steel headers. In the latest improved construction, however, the entire boiler is built of wrought steel. The tubes are weldless, being drawn by the Mannesmann process.

The Babcock-Wilcox boiler has proved itself a very suitable steam generator for electric power purposes, where smokeless steam coal or anthracite can be obtained; and, in one instance at any rate, it has given good results with inferior bituminous coal, when stoked mechanically. We have already referred to the modification of the furnace by which it may be made to use hand-fired small bituminous coal. The chief merits of this boiler are: That it may rapidly be got under steam, varied in its steaming rate or shut down, without risk of injury and without much loss of heat; that it is compact, easily accessible for cleaning or repairs, and is built up in sections, so that any part may be removed and replaced without much loss of time; and that, owing to the absence of a large cylindrical shell, the risk of dangerous explosion is reduced to very nearly zero. The chief defects of the boiler, in the author's opinion, are: That it requires in general an expensive class of fuel; that it is liable to make wet steam if not carefully managed; that it has little water room, and must therefore be fed with water continually even while making steam at an abnormally rapid rate, and it cannot regulate its pressure so well as more bulky boilers; that it is liable to become choked internally if fed with very hard feed-water; and that, through the whole of the heating surface being external to the boiler, a great deal of loss from radiation and conduction through the setting and foundations is liable to take place. Notwithstanding these liabilities to fault, the Babcock-Wilcox boiler has given excellent results in an immense number of electric power stations.

(To be continued.)

ON THE DISELECTRIFICATION OF METALS AND OTHER BODIES BY LIGHT.

BY DR. OLIVER LODGE.

Referring to a footnote to my Royal Institution lecture, reported on page 186, June 15th, Messrs. Elster and Geitel have been good enough to call my attention to a great deal of work done by them in the same direction. To make amends for my ignorance of this work at the time of my Royal Institution lecture, and to make it better known in this country, I make abstract of their Papers as follows:—

Wiedemann's Annalen, 38, p. 40.—"On the Dissipation of Negative Electricity by Sun and Daylight."

With a view to Arrhenius' theory concerning atmospheric electricity, we arranged experiments on the photo-electric power of sunlight and diffuse daylight at Wolfenbüttel from the middle of May to the middle of June, 1889. Hoor alone had observed the effect of sunlight; other experimenters had failed to find it, but we find a discharging effect even in diffuse daylight.

We take an insulated zinc dish, 20 cm. diameter, connect it to a quadrant electrometer or an Exner's electroscope, and expose it in the open so that it can be darkened or illuminated at pleasure. Sunlight makes it lose a negative charge of 300 volts in about 60 seconds. A positive charge of 300 volts is retained. The dissipation of negative electricity ceases in the dark, and is much weakened by the interposition of glass. But light from the blue sky has a distinct effect. Fill the dish with water, or stretch a damp cloth over it, and the action stops. A freshly-scrubbed plate acquires a positive charge of $2\frac{1}{2}$ volts, which can be increased by blowing.

With freshly-cleaned wires of zinc aluminium or magnesium attached to the knob of the electroscope, a permanent negative charge is impossible in open sunlight. Indeed, magnesium shows a dissipating action in diffuse evening light. Such wires act like glowing bodies. Exposing an electroscope so provided in an open space it acquires a positive charge from the atmosphere. No abnormal dissipation of positive electricity has been observed.

Wied. Ann., 38, p. 497.—Continuation of Same Subject.

Our success last time was largely due to the great clearness of the sky in June, and we wished to see if we could get the same effect at the beginning of winter.

The following is our summary of results:—

Bright fresh surfaces of the metals zinc, aluminium, magnesium were discharged by both sun and daylight when they were negatively charged; and they spontaneously acquired a positive charge, whose amount could be increased by blowing.* A still more notable sensitiveness to light is shown by the

* A fact noticed by Bichat and Blondlot.

Digitized by Google

amalgams of certain metals; viz., in the order of their sensitiveness, K, Na, Zn, Sn. Since pure mercury shows no effect, the hypothesis is permissible that the active agent is the metal dissolved in the mercury. If so, the following are the most active metals :—

K, Na, (Mg, Al), Zn, Sn.

All other metals tried, such as Sn, Cd, Pb, Cu, Fe, Hg, Pt, and gas carbon, show no action. The same is true of nearly all non-metallic bodies; but one of them—namely, the powder of *Balmain's luminous paint*—acted remarkably well in sunlight. Of liquids, hot and cold water, and hot and cold salt solution were completely inactive; consequently, wetting the surfaces of metals destroys their sensibility to light.

The illumination experiments can be arranged in either of two ways. For experiments in free space we use zinc, aluminium, or magnesium wires, or small amalgamated spheres of zinc provided with an iron rod. With these it can be easily shown that the illuminated surface of certain metals acts in the same way as a flame-collector.

For demonstration experiments the apparatus described* is better, and with this we show the following :—

Amalgamated zinc, negatively charged, discharges almost instantly in sunlight; and if near a positively-electrified body charges itself positively.

The same thing happens, though more slowly, in diffuse daylight. Red glass stops the action, but the following let some through :—Selenite, mica, window glass, blue (cobalt) glass.

Wied. Ann., *39*, *p. 332*.—*On a Checking Action of Illumination on Electric Spark and Brush Discharge.*

If sparks are just able to occur between a brass knob and a clean amalgamated zinc cathode, illumination of the latter by ultra-violet light tends to check them. [This is a curious inversion of Hertz's fundamental experiment on the subject.

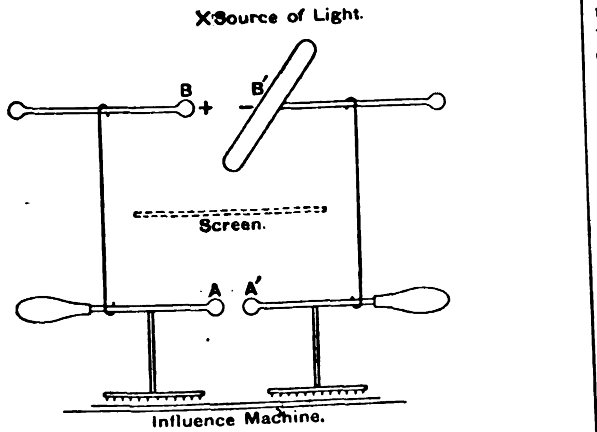

FIG. A.

Explanation of Fig. A.—B' is a brightly polished amalgamated zinc plate attached to the negative pole of a Holtz machine, with the positive knob from 6 to 10 centimetres distant. The source of light is a strip of burning magnesium ribbon 30 to 50 centimetres away. Whenever the spark is able just to choose the path B B', light shining on the zinc plate checks it and transfers the spark to A A'.

It is an effect I have not yet observed; but Elster and Geitel's arrangement differs from mine† in that the surfaces are at a steady high potential before the spark, so that light can exert its discharging influence, whereas in mine the surfaces were at zero potential until the spark rush occurred. Hertz's arrangement was more like mine, inasmuch as he illuminated the knobs of an induction coil on the verge of sparking. It appears, then, that whereas the action of light in discharging negative electricity from clean oxidisable metallic surfaces is definite enough, its influence on a spark discharge differs according to the conditions of that discharge—in cases of "steady strain" it tends to hinder the spark; in cases of "sudden rush" it tends to assist it.—O. J. L.]

Wied. Ann., *41*, *p. 161*.—*On the Use of Sodium-Amalgam in Photo-electric Experiments.*

Elster and Geitel have repeated some of Righi's experiments on the discharge of negative electricity from metals in rarefied air, and find, in agreement with him, that a reduction of pressure to about one millimetre increases the discharge velocity about six or seven times. They proceed to try sodium-amalgam exposed to daylight in exhausted tubes, and describe apparatus

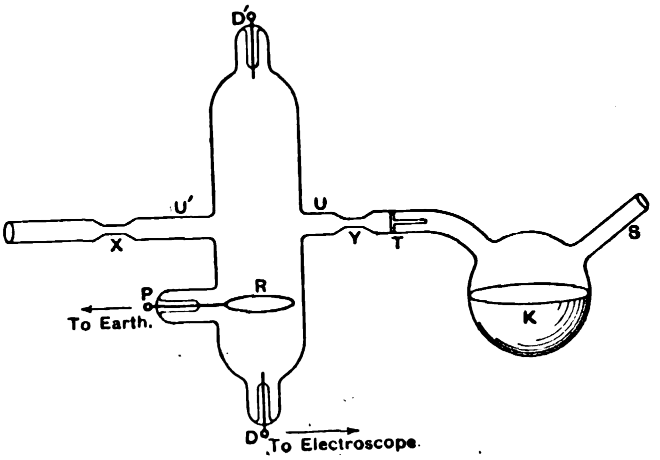

FIG. B.

Explanation of Fig. B.—The sodium and mercury are introduced through the tube S into the globe K. The tube S is then closed, a pump applied to X, and exhaustion carried on for some days. T is an open funnel sealed into the tube (as is done in some vacuum tubes made by Holtz to show a curious unilateral conductivity of rarefied gas. The object of this funnel is to permit metal from the interior, free from scum, to be introduced from K to D when the whole is tilted. Thus a bright surface is exposed to the earth ring R. It can be charged negatively, and its leak under illumination be measured, through the terminal D. Sometimes the tube is inverted, so that the active surface may be at D', further from the earth wire.

for the purpose. Such an arrangement simply cannot hold a negative charge in bright daylight, even although it be unprovided with quartz windows. Even paraffin lamps and sodium flames exert some action.

They observe that under the action of light the boundary surface of the metal and glass changes, and the metal begins to cling to the glass. They suppose that Warburg's vacuum tubes of pure sodium may behave similarly, and show photo electric sensibility.

The Same, p. 166—*On a Checking Action of Magnetism on Photo-electric Discharge in Rarefied Gases.*

The authors point out analogies between the above effects and those they had observed in the action of glowing bodies in air, and they mention Lenard and Wolf's experiments (*Wied. Ann.*, 37, p. 443), tending to show that the effect is due to a disintegrating or evaporative effect of light on surfaces. Elster and Geitel had observed that the discharging power of glowing bodies was diminished by application of a magnetic field, the effect being the same as if the temperature was lowered; and they proceed to try if the discharge of negative electricity from illuminated surfaces in highly-rarefied gas could also be checked or hindered by a magnetic field. They find that it can.

Using the light from sparks admitted through a quartz window into the vacuum tube when a negatively-charged amalgamated zinc surface was exposed near an earth-connected platinum ring, and between the poles of a small electro-magnet, they found that when the tube was full of air at 10mm. pressure the magnet had but little effect, but that at 0·15 mm., whereas without the magnet the charge of − 270 volts disappeared completely in five seconds, when the magnet was excited it only fell about half that amount in the same time. With hydrogen at 0·24mm. the result was much the same, and at either greater or less pressure in both cases the magnet had less effect. In oxygen the loss of charge was not quite so rapid; and, again, at a pressure of 0·1mm. the magnet more

* In this apparatus the mercury amalgams of K and Na are run through a fine funnel, so that the freshly-formed surface of the drops may be illuminated. Under these circumstances, while pure mercury fell from − 185 to − 175 volts in 30sec., amalgam of zinc fell from − 195 to − 116 in 15sec., amalgam of sodium fell from − 195 to 0 in 10sec., and an amalgam of potassium fell from − 195 to 0 in 5 seconds.

† *See* Fig. 22, July 6th, p. 271 or p. 155.

Digitized by Google

than halved the rate. But in CO_2 the rapidity of loss was extreme.* Either at 1·1mm. or at 0·005mm. the charge of – 270 volts leaked away completely in two seconds when the magnet was not excited; but in the latter case (low pressure) exciting the magnet reduced the speed by about one-half. At the pressure of 1·1mm. the magnet did not seem to produce an effect. With daylight the results are similar.

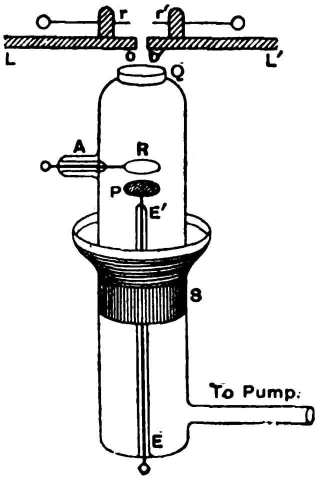

FIG. C.

Explanation of Fig. C.—P is the plate of amalgamated zinc, and R is the earth ring, as before. Ultra-violet light is introduced through a quartz window Q from a spark gap *r*. The vessel has a joint at the middle, so that the sensitive plate can be got at and changed. Magnet poles are applied outside this vessel in various positions.

The authors then discuss the meaning of this result, and its bearing on the opposition hypotheses of Lenard and Wolf and of Righi. Lenard and Wolf's view is that the loss of negative electricity is due to dust disintegrated from the surface by the action of light, dust whose existence they consider is established by an observed effect on steam jets. Righi, on the other hand, believes that gas molecules themselves act the part of electric carriers. Elster and Geitel consider that the magnetic effect observed by them supports this latter view, it being known that a magnet acts on currents through gases; and they surmise that the impact of light vibrations may directly assist electric interchange between a gas molecule and the surface, by setting up in them syntonic stationary vibrations, something like resonant Leyden jars. It is to be remembered that phosphorescent substances, such as Balmain's paint powder, exhibit marked photo-electric effect in daylight.

The unilateral character of the electric motion, and the charging of neutral surfaces by light, require special hypotheses, concerning an E.M.F. at the boundary of gases and conductors, such as Schuster and Lehmann have made.

Wied. Ann., 42, p. 564.—Note on a New Form of Apparatus for Demonstrating the Photo-electric Discharging Action of Daylight.

A vacuum tube suitable for experiments with sodium amalgam or pure sodium, or the liquid sodium-potassium alloy, is described, with the aid of which a current (shown by the

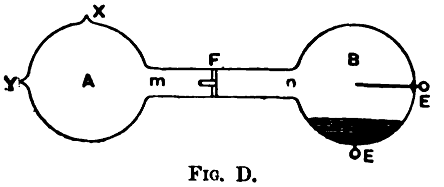

FIG. D.

Explanation of Fig. D.—A simpler arrangement, like the one above (Fig. C), whereby clean liquid alkali metals can be introduced into the experimental chamber B, from the preliminary chamber A, through a cleansing funnel F which dips its beak into the interior.

charge of an electroscope) can be maintained by a dry pile through the rarefied gas above the metal when it is illuminated from ordinary windows.

* Corresponding to the activity of this gas as found by Wiedemann and Ebert (*Wied. Ann.*, 33, p. 258), in their researches on the influence of light on ease of sparking.

Wied. Ann., 43, p. 225.—On the Dependence of the Discharging Action of Light on the Nature of the Illuminated Surface.

Experiments also on differently-coloured lights. Summary of results. The photo-electrically active metals arrange themselves in the following order—Pure K, alloys of K and Na, pure Na. Amalgams of Rb, K, Na, Li, Mg, (Tl, Zn); the same as their voltaic order. With the most sensitive term of the series a candle six metres off can be detected, and the region of the spectral red is not inactive. The later terms of the series demand smaller waves, and even for potassium blue light gives a much greater effect than red. No discharge of positive electricity is observable with these substances.

Wied. Ann., 44, p. 722.—On the Dissipation of Electric Charge from Mineral Surfaces by Sunlight.

Hitherto only Balmain's paint powder has been observed to be active among non-metallic substances. Now they try other phosphorescent bodies, and arrive at the following results:—

Fluor-spar is conspicuously photo-electric, both in sunlight and daylight, especially the variety of fluorite called *stinkfluss.*

Freshly-broken surfaces discharge much more rapidly than old surfaces.

Blue waves, and not alone the ultra-violet, have a perceptible effect on fluor-spar.

In a vacuum the mineral loses its photo-electric sensibility and its conductivity too. Contact with damp air restores its sensibility. Moistening with water weakens, but does not destroy, the sensitiveness. On the other hand, igniting the mineral destroys both its photo-electric power and its exceptional phosphorescent property.

Distinct traces of photo-electric power are shown by the following minerals also: Cryolite, heavy spar, celestine, arragonite, strontianite, calcspar, felspar, and granite.

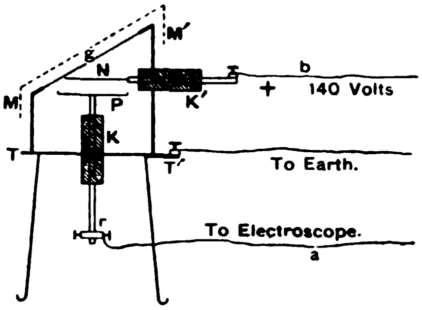

FIG. E.

Explanation of Fig. E.—Arrangement used by Elster and Geitel for exposing various phosphorescent minerals to daylight, while under inductive charge. They were put in powder in the tray P, and the transparent wire-gauze N above them was charged positively from a battery. The metal cover MM' could be removed and replaced at pleasure, and the effect on a delicate quadrant electrometer connected to P observed. By this method considerable tension can be got up on the mineral surface, notwithstanding that it is close upon zero potential. The light effect depends on tension, not potential.

The hypothesis that the power of phosphorescing when illuminated is approximately a measure of the discharging power of light has been verified in many cases; the exceptions can probably be explained by the influence which the electrical conductivity of the illuminated substance exerts on the rate of discharge of electricity from its surface. This agreement confirms the view expressed by us on the occasion of experiments with Balmain's paint, that, during electrical discharge by light, actions take place which are analogous to those of resonance. Messrs. Wiedemann and Ebert had previously been led by other considerations to the same conclusion.

We are compelled by the results of the present experiments to conclude that a more rapid discharge of electricity into the atmosphere takes place in sunlight than in darkness from the surfaces of the earth, which is composed of mineral particles charged, as the positive sign of the slope of atmospheric potential indicates, with negative electricity.

It seems to us evident that there exists a direct electric action of sunlight upon the earth, and that we have given experimental evidence in favour of the theory put forward by von Bezold and Arrhenius, according to which the sun acts on

Digitized by Google

the earth, not by electrostatic or electro-dynamic action-at-a-distance, which would involve difficulties of a theoretical character), but through the medium of the electrical forces of light waves. We hope soon to establish the consequences of this theory in meteorology in another Paper, giving the results of two years' observations on the intensity of the most refrangible rays of sunlight and of the slope of atmospheric potential.

Wied. Ann., 48, p. 338.—Experiments on the Gradient of Atmospheric Potential and on Ultra-Violet Solar Radiation.

Elster and Geitel describe the observations they have made for two years on solar radiation, at observing stations of low and high altitude, as tested by its electrical discharging power; and they plot curves of such effective radiation for days and months, along with the curves of atmospheric potential observed at the same places. These curves are of much interest, and need study. Incidentally they find that, of thewhole effective solar radiation, 60 per cent. was absorbed at altitudes above 3,100 metres; 23 per cent. of the remainder was absorbed in the layer between this and a station at 1,600 metres; and 47 per cent. was absorbed between this and 80 metres above sea level. Or, in other words, of 236 parts which enter the atmosphere 94 reach the highest observing station (Sonnblick-gipfel), 72 the middle one (Kolm-Saigurn), and 38 the lowest (Wolfenbüttel). They discuss the question as to how far the daily variation of terrestrial magnetism is due to electrical currents in the atmosphere excited by sunshine, and other meteorological matters.

[The Paper and plates are worthy of reproduction in full in the *Philosophical Magazine.*]

Wied. Ann., 46, p. 281.—On the Behaviour of Alkali Metal Cathodes in Geissler Tubes; On Photo-electric Discharge in a Magnetic Field; and On the Measure of Photo-electric Currents in Potassium Cells by means of a Galvanometer.

Results:—The resistance of a Geissler tube provided with a cathode surface of pure alkali metal is diminished by the light

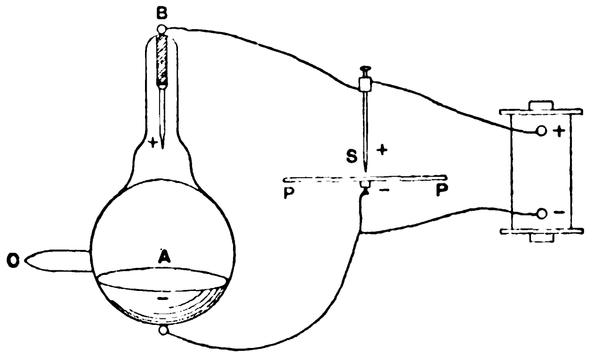

FIG. F.

Explanation of Fig. F.—A vacuum tube of rarefied hydrogen containing alkali metal as cathode, say the liquid K – Na alloy, or solid K or Na. A spark gap at S serves as alternative path, and a stream of sparks can occur to the plate P in the dark. But when light falls on the surface A, this stream of sparks can cease, showing that the resistance of the vacuum tube is diminished.

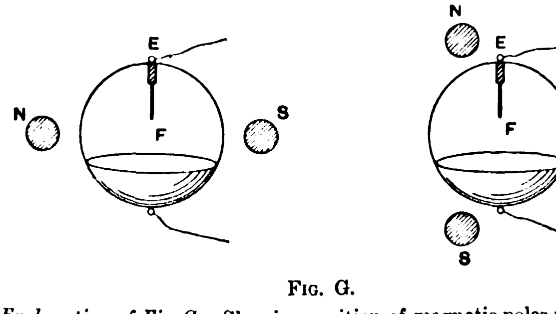

FIG. G.

Explanation of Fig. G.—Showing position of magnetic poles with respect to the vacuum tube discharge. With the poles *across* the line of discharge, as in Fig. on left, excitation of the magnet opposes the leak from the surface. With the poles as in Fig. on right, the discharge is not much affected—it is even sometimes slightly increased.

from the sparks of an induction coil; especially when the pressure is ·1 to ·01mm. of mercury. The resistance which rarefied gas opposes to an electric current in a magnetic field is greatest in the direction normal to the magnetic lines. The changes of resistance effected by any kind of light in a vacuum tube with alkali metal cathode can be measured galvanometrically. (A Daniell cell gives 100 divisions on a Rosenthal

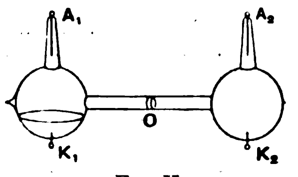

FIG. H.

Explanation of Fig. H.—Potassium vacuum bulbs containing ½ millimetre of hydrogen mounted and connected to battery and galvanometer, and arranged as a photo-electric photometer.

galvanometer when coupled up through such an illuminated tube, each division meaning about 10^{-10} ampere).

Wied. Ann., 48, p. 625.—On the Photo-electric Comparison of Sources of Light.

Attempts to make such a potassium cell into a photometer.

Wied. Ann, 52, p. 433.—Further Photo-electric Experiments.

Plates of platinum, silver, copper need exceedingly ultra-violet light before they show any photo-electric power; zinc, aluminium, magnesium show it for visible violet and blue light; the alkali metals, in an atmosphere of rarefied hydrogen, advance their range of sensibility into the spectral red; while under the most favourable conditions they show a sensibility only inferior to that of the eye itself. The Authors now use galvanometric methods of measuring the effect, instead of only electrometers, and they arrive at the following results:—

(1) The three alkali metals Na, K, Rb, have different sensibility for differently-coloured lights. For long waves their order of sensibility is Rb, Na, K; though Rhubidium is far exceeded by the other two metals in white light.

(2) Illumination of a plane alkali-metal cathode surface with polarised light causes greatest discharge if the plane of polarisation is normal to plane of incidence; and least, if the two coincide.

[This is a most remarkable observation. Its probable meaning is that the electric oscillations of light are photo-electrically effective in so far as they are normal to the susface on which they act; while electric oscillations tangential to the surface are scarcely operative. Different angles of incidence must be tried before the proof is complete. O. J. L.]

(3) Electric oscillations of very short period, such as are given by a Hertz oscillator, are commutated by illumination in the presence of alkali metals in rarefied gas, so as to be able to set up a constant electric tension in the gas.

[A Zehnder tube* was used, and the momentary phases of the oscillation during which the metal is negatively charged are apparently taken advantage of by the illumination.]

(4) The photo-electric dissipation shown by powdered fluor-spar is dependent on the colour of the mineral, in such a way that the deepest blue violet or green specimens are the most sensitive.

COST OF ELECTRICAL ENERGY.

In order that those of our readers who do not happen to be in receipt of copies of the *Journal* of the Institution of Electrical Engineers may have an opportunity of perusing the communicated remarks on Mr. Crompton's recent Paper, as well as the author's written reply, we publish these below in full:—

Mr. A. BROMLEY HOLMES: Mr. Crompton's useful and interesting Paper will be studied with advantage by all engineers connected with electrical supply. In his prophetic estimate of the future selling price of electrical energy, which he fixes at 3d. per unit, Mr. Crompton omits to make any allowance for depreciation. The experience of those who have been engaged in manufacturing businesses shows that it is not sufficient merely to provide for the annual cost of repairs necessary to maintain the plant in first-class working order, but that mere lapse of time entails a depreciation in value, and the consequent necessity of setting aside a depreciation or renewal fund to provide for the expenditure from time to time necessary to keep the plant up to date.

* See *The Electrician*, June 15th, p. 188, Fig. 13.

Digitized by Google

In a Paper read before the Liverpool Engineering Society a few months since, the writer estimated the cost of electricity to the consumer in the near future on a business selling two million units per annum at the following figures:—

	Pence per unit.
1. Works cost, including maintenance	1·5
2. Management	0·5
3. Profit	1·5
Total	3·5

To which was added an allowance of 1½d. per unit for depreciation reserve.

Mr. Crompton's figures for the corresponding items are as follows:—

	Pence per unit.
1. Works cost and maintenance	0·9
2. Management	0·42
3. Profit	1·68
Total	3·0

As the writer's figures were based on sales of two million, and Mr. Crompton's on five million units per annum, there is a very close correspondence between them.

In Table III. Mr. Crompton gives, under item N, the evaporation obtained by Lancashire boilers in Liverpool at 5lb. of water for each pound of coal. Mr. Crompton adds a note of interrogation to the 5lb.; and to make his table accurate this note of interrogation should be replaced by 0·48, as the evaporation, averaged over a long period, has been 5·48lb. of water per pound of high-class Lancashire slack. Mr. Crompton is in error in supposing that in the northern counties little or nothing is said if smoke is produced. In Liverpool (and no doubt also in Manchester and other towns) the Corporation inspectors keep a most vigilant watch on the chimneys; but a Lancashire boiler, if properly worked, produces very little smoke and causes no nuisance. The writer cannot help thinking that Mr. Crompton's experience with Lancashire boilers at Chelmsford (item J in Table III.) has been unfortunate, and that further experiment may enable him to secure better results. The results given in last column of Table VI. are comparatively valueless unless accompanied by some information as to the average loads at which the engines are worked. In the early days of a supply station the unit size of plant selected is usually too large for the working conditions of the station, but as the demand increases this disadvantage gradually disappears. A direct-acting high-speed engine which at full load will produce one unit per hour at the dynamo terminals with 30lb. of steam, will require approximately double this amount of steam, and consequently of fuel, when working at one-third load. From this point of view Table VI., though of great interest historically, requires further details (which have unfortunately been impossible to obtain) to make it of great practical value. Mr. Crompton does valuable work in calling attention to the great waste of fuel arising from the use of small independent engines for pumps and similar purposes. In the Liverpool supply stations considerable economy has been effected by replacing the stoker engines by electromotors, and it is under consideration to deal with the pumps in a similar way. Mr. Crompton is to be congratulated on the extremely favourable rates of maintenance which he has attained, as set forth in Table VIII. Unless the capital value of the accumulators is taken at an unduly high figure, the annual maintenance rate of 3½ per cent. is one of which he may be justly proud; it will be a matter of great interest to supply station engineers to learn in the future if this remarkably low rate of maintenance can be continued during the succeeding equal period of four years. Mr. Crompton must have expended a great deal of time and trouble in collecting and arranging the valuable information contained in his Paper, and deserves the gratitude of all interested in electrical supply for his generosity in publishing the results of his experience so fully and freely for their benefit.

Mr. W. D. HUNTER: In a Paper dealing with the cost of electrical energy to consumers, it appears to me that the method adopted by Mr. Crompton, in leaving out of consideration Directors' fees, salaries, and expenses, does not show the true cost of production. I do not think the cost of management is outside the province of engineers, but is just as much an item to be considered as the choice of the system used, and the skill of the designer, and the interest to be paid on the capital expended. To my mind, the right thing to do is take the TOTAL cost of production, plus a reasonable rate of interest on the capital employed to produce the energy sold to consumers; and the argument in favour of this is that one company may produce energy at a very low cost, but such a result may only be obtained by a large capital expenditure.

With regard to Table VI., in which the comparison of fuel used by different companies is given, the figure opposite my Company (viz., the Newcastle and District Electric Lighting Company, Limited) of 310 British thermal units used per watt-hour, is *wrong*; it ought to be 204, and this I pointed out to Mr. Crompton before the reading of his Paper. As the result of careful experiment at our works, I estimated the average production of steam over the year to be 5lb. per pound of coal used—*i.e.*, the calorific value of the fuel used by us in conjunction with our ordinary method of stoking was only half that of Welsh coal evolving 14,500 British thermal units. I may further say that in the case of my Company, after the experience of the past year, it has been found false economy to use a common quality of coal, in spite of its low cost. The fact, however, remains that such coal was used, with the result shown by the figures following:—

Total coal used during the year was 4,698 tons.
Calorific value, 7,250 British thermal units.
Total units sold, 372,922.

$$\frac{4{,}698 \times 2{,}240 \times 7{,}250}{372{,}922{,}000} = 204.$$

Mr. T. P. WILMSHURST: Mr. Crompton's interesting Paper, as might be expected, resolves itself into a vindication of the supposed advantages of low tension over high tension, water-tube over Lancashire boilers, and direct over rope driving. It is open to doubt, however, whether any comparison can fairly be drawn between the working results of a station serving only a compact area, and one serving a scattered and perhaps thinly-populated area. If any such comparison can be made, surely the distance from the works to the farthest lamps, or the relative areas supplied, should be taken into account; but this consideration has been omitted from the Paper—and perhaps wisely. Examination of *The Electrician* supplement of January 5th shows that at the stations mentioned in Table VI. the distance from the works to the farthest lamps is, with the high-tension works, on the average *more than three times* as great as that from the low tension stations. Had the low-tension stations had to serve similar areas to those of their rivals, would not the relative efficiencies have been widely different?

Apropos of Lancashire boilers, Mr. Crompton remarks, "At any rate, the electric works using Lancashire boilers have not hitherto shown at all well in comparison with other types." Published records, however, appear to prove the *exact opposite*. The works using Lancashire boilers appear in the front rank for economy—notably Birmingham, Bradford, Liverpool, Brighton, Leeds, Newcastle, &c.; and the lowest works costs on record of 2·10d. are obtained in a station using these boilers!

Rope driving also comes in for its share, and perhaps more than its share, of condemnation. Examination of the before-mentioned supplement shows that the majority of stations now at work use ropes or belts; indeed, excluding the London stations, where ground space is the all-important consideration, the preponderance in favour of ropes becomes still more marked. It is a curious commentary on Mr. Crompton's criticisms that in the stations now under construction, designed presumably on the accumulated experience of past years, rope driving, Lancashire boilers, and alternating currents are being used in overwhelming proportion.

Mr. WILLIAM E. GRAY: Although I made no attempt to join in the verbal discussion of Mr. Crompton's Paper, in view of the time allowed for this being necessarily limited, I wish to join with other members in thanking the author for the very valuable paper he has laid before us on a subject which is of great interest, and which, owing to the difficulties surrounding it, has hitherto been dealt with incompletely. The data given are of exceptional value; but I cannot agree with many of the deductions drawn from these by the author, and to such points of difference I shall confine my remarks.

In referring to fuel, the author appears to consider that Welsh coal is the best under all conditions. Although this may be so with regard to London, where smokeless combustion is an essential; in other towns, with proper boiler arrangements, other classes of coal can be used with advantage. With a view to obtaining the maximum of fuel economy in the Silvertown Telegraph Works, where over 40 boilers are in use, we have been engaged for a number of years in the systematic test of coal; and, although the results cannot be considered as comparative with results obtained under other conditions, still in themselves they are of value. The type of boiler used for these tests is the Lancashire, with Galloway tubes, and fitted with mechanical automatic stokers; and the tests were uniformly carried out, admitting to the boilers feed water at 60° F., and evaporating steam at 60lb. pressure, the length of test extending over at least 12 hours. The boilers were worked at their normal rate in all cases, and the tests of the various kinds of coal were carried out in the same boilers, to ascertain which coal was most suitable and economical for use with these boilers. No test was made on the percentage of water carried over by the steam, and the following results were obtained:—

CLASS OF FUEL.	Lbs. of water evaporated per lb. of coal.	Cost of fuel, in pence, per 100 gals. evaporated.
Midland coal, average quality	5½	7¾
Durham coal, average quality	7⅓	7
Welsh coal, small nuts	6¼	10

The cost of fuel does not include delivery in London, but is probably a fair average for most towns favourably situated for fuel transport, and naturally on the cost of transport would greatly depend the class of coal to be used. But the above goes to show that, even in London, an economy can be effected by using Durham coal, if such steps are taken as are necessary to prevent any inconvenience arising from its use.

In considering the type of boiler to be used, the author appears to have somewhat lightly treated the claims for consideration of the Lancashire boiler. Where rent is high, water good, and rapid steaming an important factor, the water-tube and locomotive type boiler present great advantages; but in many towns rent is not high, water is not good, and rapid steaming—due to disposition of plant—is not an absolute necessity; in such cases the Lancashire boiler can be used with advantage. It may be objected that the question whether the water is good or not should be considered apart from the boilers. Unfortunately, this cannot always be done, even if the size of the plant and volume of water to be treated justifies the erection of a purifier, as we cannot always be certain that the water passing through will be purified completely. The use of a purifier will, we know, allow us to use water which would otherwise be useless, and no doubt aids us in making indifferent water serviceable; still, we cannot ask for perfection in the purifier, and must seek for a boiler which will deal economically with the water at our disposal, whether purified or not, according to circumstances. The amount of moisture in the steam, and cost of upkeep of the boilers, must also be taken into consideration where economy is sought.

Digitized by Google

The author refers to superheaters. The economical advantages of these, properly applied, is undoubted; but before deciding to adopt this system on the score of economy of steam consumption alone, would it not be well to consider the cost of upkeep? Even under the favourable conditions mentioned by Prof. Unwin as obtaining in Alsace, I am assured that the cost of maintenance is an important factor, and that many of the engineers who have closely followed the experiments carried out there have decided to await further improvements before adopting this system.

Dealing with engines, Mr. Crompton is apparently prepared to pin his faith to the high-speed type, directly coupled to the dynamo. Although there is no doubt that, owing to the great abilities of the late Mr. Willans, much has been done to improve this type, slow-speed engine makers have not been idle; and, as mentioned by Mr. Crompton, Carels, Treves, Sulzer, and other makers can produce engines which will be difficult to improve upon from the point of view of economy of steam consumption. The objection to the large space demanded for these engines as compared with that required for the high-speed type is, after all, a question of rent plus cost of maintenance; and it remains to be proved, for the high-speed engine, whether it can compete favourably on these grounds. In referring to the cost of oil for engines, it is to be regretted that the author draws no distinction between vertical and horizontal slow-speed engines.

Attention is drawn to the classification of Table VI., and it is inferred that the difference in cost per unit is due to the difference in mode of drive. If this were really so, it would go far to support the author's contention that direct drive is to be preferred to rope drive; but the Table shows that the rope-driven plant is nearly invariably alternating current, while the direct is continuous current. I must leave to others to decide whether the comparison is a fair one between these two systems, and confine myself to saying that it certainly is not a fair comparison between the relative values of the two drives. This the author admits when he shows that the initial efficiency of the high-speed plant described is little greater than that obtained with a horizontal slow-speed engine with rope drive. What the comparative efficiency would be after, say, six years, he does not tell us. Whatever the disadvantages of a rope drive may be, it certainly has the advantage of being a flexible, instead of a rigid, connection between engine and dynamo.

Although the author gives us no comparative costs of maintenance for the engine and boiler he prefers, he at least gives us the cost of maintenance of his underground system in use by the Kensington and Knightsbridge Company, his results being based on the last four years' working; but, as he gives no cost for maintenance of continuously-insulated cables underground, I am at a loss to understand how he arrives at the conclusion that his system is less cos ly. To fill his omission, I give the figures published in the report of the Metropolitan Electric Supply Company.

Mains, including cost of laying mains, £141,639. 0s. 8d. Repairs, maintenance, and renewals of mains of all classes, including materials and laying the same, £26. 15s. 8d. The system here employed is high-tension where the strains that the dielectric is subjected to are greater than those borne by the mains of the Kensington and Knightsbridge Company. As part of the cables were laid over four years ago, the comparison is a fair one. The result--*i.e.*, a cost of maintenance of less than 1-50th per cent.—does not bear out Mr. Crompton's contention.

In conclusion, if the reading of Mr. Crompton's Paper tends to convince electrical engineers that no standard type of plant is possible; but that the plant must vary according to the conditions of work, which must be carefully considered before the machinery is selected; then, in addition to the value of the tables he gives, the author's Paper will have done much to prevent the industry following in a groove from which it will be difficult to stir, and which may lead to utter failure in many cases.

Mr. ARCHIBALD SHARP (*communicated*): No reference has been made in the discussion to the cost of energy for electric traction, possibly on account of its relatively much smaller importance on this side of the Atlantic, as compared with the cost of energy for electric lighting. At the generating station of an electric railway or tramway the peaks of the load curve have bases of about one-quarter to one-half a minute, instead of two or three hours as in an electric light station. These peaks occur at small intervals, corresponding to the time of starting of the trains or cars. The maximum ordinate of the load curve may be twice the mean ordinate, in which case the engines—which must be of power equal to that denoted by the maximum ordinate—will be running most of the time at half-load, with a corresponding low efficiency. If engines of power just equal to that denoted by the mean ordinate of the load curve could be used, in conjunction with storage of energy for the peaks of the load curve, the efficiency of the engines would be increased, and the cost of the energy diminished. A fly-wheel of quite reasonable dimensions can be designed to give the necessary store of mechanical energy. Let W be the weight of the rim in tons, V the linear velocity of the rim in feet per second, then the energy stored in the rim will be

$$\frac{W V^2}{2g} \text{ foot-tons, } = \frac{W V^2}{948 \cdot 8} \text{ H.P.-minutes.}$$

If a variation of speed of 2½ per cent. above and below the mean speed be allowed, the energy available will be $\frac{W V^2}{94 \cdot 8}$ H.P.-minutes. The greatest safe speed of rim of large cast-iron fly-wheels of the usual type seems to be about 75ft. per second, though there are cases in which a speed of 100ft. per second is reached. Taking a mean speed of 75ft. per second, and a variation of 2½ per cent. above and below the mean, to get 100-H.P. minutes available, 168 tons would be required in the rim, which is prohibitive. I have designed a high-speed fly-wheel which can be safely run up to a speed of 300ft. per second. The distinctive features of its construction are illustrated in Figs. 1 and 2. The nave of the wheel is suspended from the rim by a series of steel loops; one loop forming a pair of spokes is shown thickened. The ends of the pair of spokes are fastened to the rim by nuts. The portion of the spokes in contact with the nave lie in helical grooves cast on the latter. There is absolutely no fastening of the spokes to the nave beyond that due to friction. The rim, being supported at small intervals by the numerous spokes, is nowhere subjected to large bending stresses due to centrifugal force, as is the case in large wheels with a small number of arms. It may, therefore, be run at a much higher velocity with safety. A wheel with mild steel rim and steel spokes may be safely run at 300ft. per second linear speed of rim. At this speed, and with 2½ per cent. variation above and below the mean, 10½ tons weight of rim would be required to get an *available* storage of 100-H.P. minutes. Assuming that the form of the largest peak above the mean line is triangular, with a base half a minute long, the top of the peak would be 400 H.P. above the mean power required,

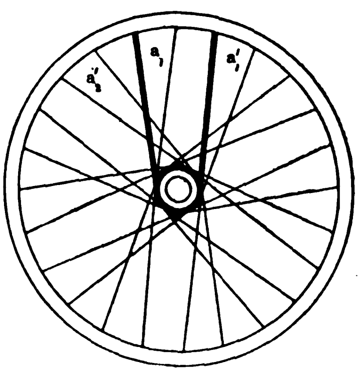

FIG. 1.

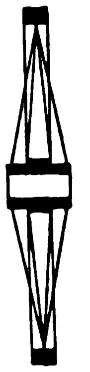

FIG. 2.

and the fly-wheel would therefore be equivalent to an engine of 400 H.P. To get the above necessary high speed the fly-wheel would, in most cases, be fixed on the same shaft as the armature of the dynamo, a simple friction coupling affording a provision against damage by short-circuiting. The dynamo would still have to be of capacity equal to the *maximum* ordinate of the load curve, though the engine need only be of power equal to the *mean* ordinate. The smaller the number of trains driven from the central station the greater is the ratio of the maximum to the mean ordinate, and therefore the greater will be the saving effected by the use of such a fly-wheel accumulator. The saving is not only effected in first cost of engines, but also in working expenses; the steam consumption per I.H.P. being, as is well known, much less in an engine working full power than in the same engine working at half load.

(*To be continued.*)

THE MECHANICAL EFFECTS OF ELECTRIC WAVES.

That electro-magnetic waves are capable of producing mechanical effects upon suitably suspended resonators has been proved by Peter Lebedew, who gives an account of his results in No. 8 of *Wiedemann's Annalen*. The primary conductor used was a Lecher wire system 28m. long. This system, which cannot well be used as a source of waves owing to its excessive damping, was used to excite a *vibrator* of suitable wave-length. A very light resonator was suspended by a torsion thread near the vibrator, in such a manner as to be excited by the vibrator, and also turned by the mechanical forces brought into play, the amount of force being measured by the torsion. To correct for the varying excitation of the vibrator, the latter was controlled in each case by an *indicator* constructed after the fashion of an induction dynamometer or an electrometer, accordingly as it was the magnetic or the electric component of the oscillation that was brought into play. The magnetic vibrator consisted of a piece of zinc 20cm. broad and 65cm. long, bent double, so that the ends formed two condenser plates opposite each other, the capacity of this condenser being adjusted by varying the distance between the plates. The magnetic resonator consisted of a coil of four turns of fine silver wire, whose terminals were connected with a couple of electrometer needles, whose relative positions determined the capacity of the condenser formed by them, and hence also the pitch of the resonator. The whole was mounted on a glass rod, with the plane of the coils vertical and suspended by a quartz fibre. The magnetic indicator was a closed ring of fine silver wire suspended inside the vibrator with the same orientation as the resonator. For the electric component modified forms of vibrator, resonator, and indicator were employed, only permitting the action of electrical forces. As a result of the experiments performed with these instruments, it was found that both types of resonators behaved in the same manner. The effect increased as the "pitch" of the resonator approached true resonance, and suddenly changed sign when that point was reached. When they were "tuned" higher than the vibrators they were *attracted* by the incident wave system, as shown, for instance, in the magnetic resonator by its tending to turn its plane into a position parallel to that of the vibrator. When the resonator was tuned lower repulsion took place, both attraction and repulsion being strongest in the neighbourhood of unison.

Cases for binding Volume XXXII., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

SPECIAL NOTICE.

With this week's issue of "THE ELECTRICIAN" is published a Supplement containing a Full Report of the Proceedings at the Celebration of the Twenty-Fifth Anniversary of the Establishment of Submarine Telegraphic Communication with the Far East. This Supplement is issued gratis, and complaints of non-receipt should be sent immediately to the Publisher.

With the number for July 20th, was issued (Gratis to Subscribers) a Supplement Large Sheet "Practical" Wiring Chart.

OCEAN TELEGRAPHY AND THE IMPERIAL INSTITUTE.

The brilliant gathering which assembled last Friday evening to celebrate the twenty-fifth anniversary of submarine telegraphy to the far East would, in any case, be a memorable incident in the career of the companies to whom we owe that great enterprise. But the occasion rises to one of truly national import when we consider the distinguished and illustrious personages who honoured it with their presence, and the building in which they met. The Imperial Institute is, indeed, the most fitting place that could have been chosen for a commemoration festival of this kind; but that its vast resources were placed at the disposal of the entertainers is a gratifying proof that they had not over-rated their title to be honoured as pioneers in the imperial work which that Institute was founded to consummate. Proud as they may be of their achievements in the past the promoters of ocean telegraphy have, if possible, still greater reason for pride in the fact that time and patience have brought the reward which for long was grudgingly withheld. One has only to cast an eye over the list of guests who sat down to the banquet or were present at the reception following, and to read the congratulatory speeches and telegrams, to be convinced that the great undertakings which were launched a quarter of a century ago amidst mistrust and forebodings, and persevered in with but lukewarm encouragement for a

Digitized by Google

number of years, are now receiving the full recognition and applause which they so justly deserve.

After this lapse of time the commercial risks, the electrical difficulties, the engineering obstacles which had to be overcome in the laying of this vast system of submarine cables, are apt to be forgotten, or treated as of little account. But it is impossible to speak too highly of the courage and determination of those who had to face these difficulties for the first time, and who manfully stood to their task until its triumph was assured. The commercial insight which inspired the undertaking, without any known data to guide it, is something to strike us with wonderment even now. Not less so are the social and political consequences, perhaps not altogether unforeseen, which have resulted from a successful adventure dictated primarily in the interests of trade. The whole world is, one might say, now on speaking terms; a fact which needs only to be named to indicate its profound and far-reaching consequences. What those consequences may be are beginning to be realised; and nowhere so keenly as at the National Institute, which gave Sir JOHN PENDER and his colleagues so hearty a welcome last week. That the cable companies which connect the mother country with her children and dependencies in the far East should receive special distinction, reflects the highest credit not only on the hosts but on the guests. Whatever may be the mission of the Imperial Institute in the future, its present work could not have been begun, it would not have been so much as dreamed of, and it certainly could never be fulfilled, but for the cheerful and efficient help which submarine telegraphy is able to render. We heartily join in the good wishes which were showered upon the representatives of the cable companies from every quarter of the globe.

CENTRAL STATION PRACTICE.

The publication of No. 113, Vol. XXIII., of the *Journal* of the Institution of Electrical Engineers affords additional interest to the discussion of Mr. CROMPTON'S Paper on the "Cost of Electrical Energy" by giving the full text of Mr. CROMPTON'S written reply, together with communications from several members who did not speak at the meetings. There is little or nothing in the nature of a departure from the beaten track of the spoken discussion, in the communicated comments, with the exception, perhaps, of Mr. GRAY'S remarks on the relative merits of continuously-insulated and bare mains, and the observations by Mr. SHARP on the mechanical difficulties met with in engines for electric traction. Everything else runs in well-worn grooves: opinions on the relative values of Lancashire and water-tube boilers, on the utility of rope drives, and on the merits of large slow-speed engines, and other matters which had been discussed very fully by the speakers. These opinions, however, come from very good men, and are valuable additions to the discussion. It is worthy of notice, for instance, that almost all those who have sent written communications, including Messrs. BROMLEY HOLMES, WILMSHURST, and GRAY, have sided with the speakers who advocated Lancashire boilers. May we not fairly say that all attempts to pronounce a stereotyped judgment, either favourable or otherwise, on any particular type of boiler, are hasty and ill-judged? In a question of this sort local conditions are of supreme importance, and mere generalisations count for very little. But electrical men have from the beginning shown a strong tendency to let their practice run in grooves; and, like a flock of sheep, they follow whomsoever has sufficient initiative ability to strike out along any new line, or to condemn any old one. One season they shout the praises of compact, quick-steaming boilers; the next they are all agog with thermal storage, hot water and bulky steam generators; and anon they follow the beck of some leader who points them back to the rapidly-steaming type of boiler from which they went astray. But, among the vacillating multitude, there are some few who have the sense to think and experiment for themselves, and the courage to stick to their own conclusions. Among these latter Mr. CROMPTON takes a foremost place; and he expresses his conversion back to water-tube boilers with a conviction and sincerity as genuine as when, three years ago, he gave expression to directly opposite views. In the interval Mr. CROMPTON has made careful and extensive trials of the two types of boilers concerned; and, even if unable to accept his conclusions, no one can fail to give them the highest respect and consideration.

Two of the new contributors to the discussion, Mr. GRAY and Mr. WILMSHURST, side with Prof. UNWIN in favourably regarding the use of slow-speed engines. They even go further and praise the rope drive! Against this latter view we may set the conversion of Mr. RAWORTH, of the Brush Company, from rope-driving to direct driving. While, against the advocates of the slow-speed engine for electric lighting stations, we have the statement by Mr. CROMPTON that even among the makers of these engines "a feeling in favour of high-speed engines for electric supply works has already set in;" and we may further remark that the Americans, who have up till recently been strongly in favour of geared slow engines, are now telling us of the highly original discovery they have made and propose to put in practice, viz., that direct quick-running engines are a better thing. We cannot agree with Mr. CROMPTON in his assertion that the economic advantages of high speed, superheating, and steam jacketting, can be superadded to one another. Of course, it is possible to effect a given economy by any one of them, or partially by all three; but the full benefit of any one cannot be tacked on to the full benefits of another. Mr. WILLANS has shown, for instance, that when his engine is run at a certain high speed, the whole of the initially-condensed steam is re-evaporated during expansion. Not quite as favourable a result can be obtained by jacketting a slow engine. But if the two conditions are combined, the result will be a positive injury to the efficiency.

We do not know, in the whole range of engineering materials, of anything we could recommend as being safe to use for the flywheel proposed by Mr. SHARP. It is not merely that the conditions during the time the wheel would be running steadily at 300ft. per minute are, to say the least of it, a trifle risky; but there is the additional consideration that one cannot suddenly impose the excessive load caused by the starting current in a large electro-motor without enormously adding to the already heavy stresses in the parts of the flywheel; besides which, what may be expected to happen if the engine runs a little too fast? The usual factor of safety would be insufficient to meet the special case of a flywheel designed for such heavy work; and the outlook for the discovery of a material which would render Mr. SHARP'S design reasonably safe is, at the present moment, a rather unfavourable one. Mr. SHARP suggests the use of mild steel; but our estimate of the stress in such a flywheel would seem to indicate that even with an excessively low allowance for a factor of safety this material would be inadequate. Indeed, we are inclined to think that mild steel would reach its ultimate stress long before the conditions proposed by Mr. SHARP could be attained.

Mr. CROMPTON disposes of the question of the antiquation of plant in a somewhat off-hand manner. He argues that the

Digitized by Google

creation of an antiquation fund practically amounts to raising capital at the present time for use at some future time. Better not do it, he says, in effect; it is far better to let the men of the future raise capital for themselves as they want it. Of course, if the antiquation idea be carried logically to the bitter end, which its originator probably never dreamt of, we ought to set aside a sum not only sufficient to purchase new electrical plant when the existing plant becomes antiquated but also sufficient to obviate any necessity arising, at any time in the remote future, for the purchase of any form of apparatus, electrical or otherwise, which might be required to do what the present electrical plant is now doing. What a pity the gas companies did not think of doing this for us, and actually do it, in the early days of gas lighting!

ON IMPULSIVE CURRENT-RUSHES IN INDUCTIVE CIRCUITS.

BY ALFRED HAY, B.SC. (EDIN.).

(Continued from page 297.)

§ 16. The curves shown in Fig. 6 require a few words of explanation. The switch was closed at the instant when the E.M.F. was passing through its zero value, and opened at the end of a positive half-wave of current. Referring to Fig. 5, we find 2,000 C.G.S. lines per square centimetre as the initial magnetic induction at the instant of switching on. This gives us the starting point of the abnormal magnetic induction curve shown in Fig. 6. We may now plot the abnormal hysteresis loop by taking corresponding values of the current and magnetic induction; as before, the current scale may be converted into a scale of magnetic force by multiplication by the factor 2·32 (§14). This abnormal hysteresis loop is shown in Fig. 7. The loop starts from the point corresponding to an induction of about 2,000, and reaches a maximum induction of about 6,700, or 3·35 times the normal maximum. The lowest point on the descending branch of the loop corresponds to an induction of about 1,150. Here the descending branch of the loop terminates. The loop then begins to ascend, crosses itself, and reaches a much lower maximum of magnetic induction (about 6,100) than in the first case. The same process is then repeated over and over again until the normal hysteresis loop (shown dotted in Fig. 7) is eventually reached. Roughly, we may describe the action as a gradual creeping down of the abnormal loop along the axis of magnetic induction, combined with a sort of shearing parallel to the axis of current.

Strictly speaking, in choosing 2,000 as the starting point of the abnormal magnetic induction curve, we have committed a slight inaccuracy, for a reason to be explained presently. In obtaining the curves shown in Fig. 6, the current, after having been switched on, was kept on for a little over 5½ periods, and then switched off. Now, during this time, the current has not had time to settle down completely into its normal state, so that the initial magnetic induction of the iron is, probably, somewhat higher than 2,000. In order to find whether there was any appreciable difference between the magnetic state of the iron at the end of 5½ periods, and its state after 6½ periods, the experiment was varied by keeping on the current for 6½ periods instead of 5½. It was found that this reduced the maximum value of the current during the first half-wave from 7·35 to 7·03, or by about 4 per cent.

§ 17. A comparison of the curves given in Fig. 6 with those given in Fig. 3 is instructive; it shows us that the general nature of the phenomenon is the same in both cases, but that the distortion of the waves is incomparably greater in the circuit containing iron. The question thus arises, what is this greater distortion due to? Dr. Fleming, in the Paper alluded to in § 1*, was the first to point the way towards an explanation by suggesting that the "rush" depends entirely on the relation between the initial magnetic state of the iron and the phase of the E.M.F. at the instant of switching on. A number of interesting experiments in support of this view are described by Mr. Mordey in the discussion on Dr. Fleming's Paper. With the arrangement of apparatus used in the present experiments it becomes possible to determine with fair accuracy the connection between the current-rush and the phase of the current at the

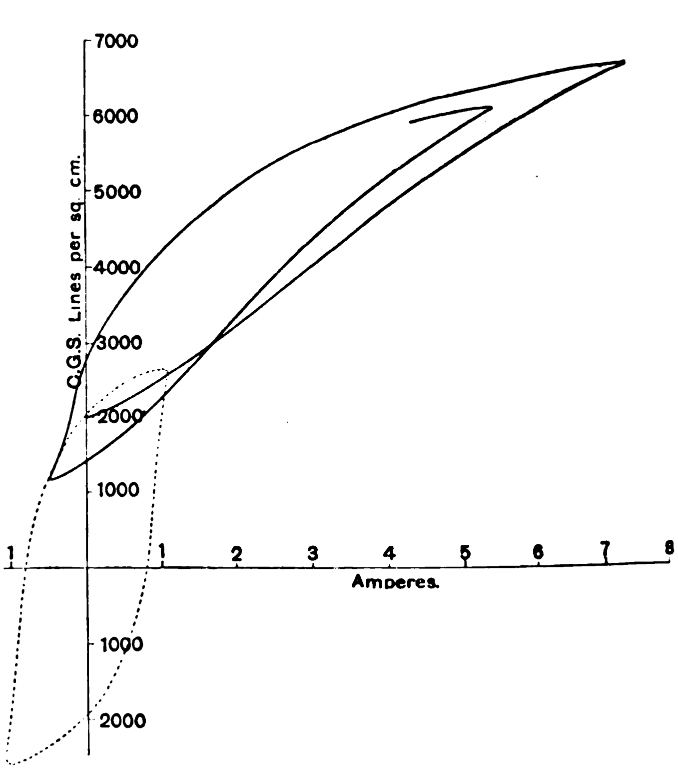

FIG. 7.

instant of switching off. This relation is shown in Fig. 8, where the abscissæ denote the values of the current at the instant of switching off (on the supposition that the current has settled down into its normal state), and the ordinates the greatest values of the current during the first half-wave. The switch is supposed to be closed at the instant of zero value of the E.M.F. This diagram brings out very clearly the following points:—(1) If the switch is opened when the current is diminishing *numerically*,

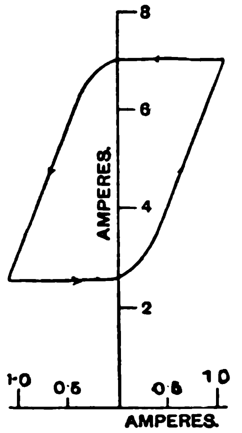

FIG. 8.

then the exact point on the current-wave at which the circuit is broken is immaterial, since the iron always returns to the same state. (2) If the switch is opened when the current is *increasing* numerically, then a very slight difference in the instant of switching off may produce a considerable variation in the "rush." (3) If the switch is closed at the instant when the E.M.F. has a small value, there will always be an abnormal current-rush, *quite independently of the magnetic state of the*

* "Experimental Researches on Alternate Current Transformers," *Journal* of the Institution of Electrical Engineers, Vols. XXI. and XXII.

Digitized by Google

iron. Thus we see, from Fig. 8, that there will be a current rush $= \frac{2\cdot56}{1\cdot09} = 2\cdot35$ (§ 3) even when the magnetic state of the iron is least favourable to the production of a "rush."

§ 18. Between the enormously distorted waves of Fig. 6 and the normal waves of current we may have all intermediate stages. One of these is shown in Fig. 9. It is here given on account of two points of interest which it presents, the peculiar *shape* of the current waves, and the exceedingly small amount of damping. It is obvious that these waves will persist throughout a very large number of periods.

We may now consider generally the action which takes place during a current-rush. In all the experiments so far described no distortion of the primary E.M.F. wave was noticed. We may therefore suppose that the primary E.M.F. is not appreciably affected by the rush. When the switch is closed the induction begins to increase comparatively slowly with the current, so that the latter reaches a value greatly in excess of its normal value. This means that during the first half-wave the

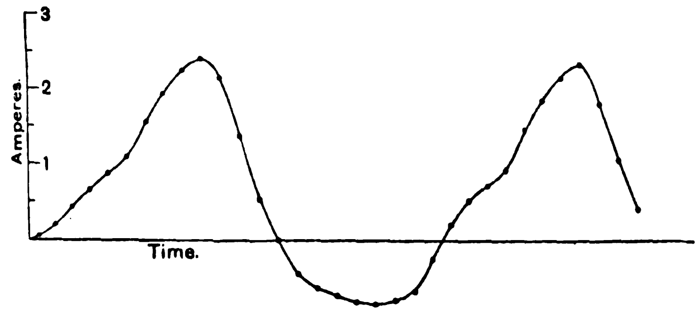

Fig. 9.

drop due to resistance is considerable, and the counter E.M.F. small. We thus get an abnormally small half-wave of counter E.M.F. (or secondary E.M.F., the magnetic leakage in the transformer used being quite negligible). The initial magnetic induction wave is raised considerably above the time-axis; ultimately it settles down into its normal state. Now since the magnetic induction is the integral of the counter E.M.F. it is obvious that the gradual lowering of the magnetic induction wave can only take place in virtue of the half-waves of counter E.M.F. being large and small alternately. We should therefore expect the secondary E.M.F. wave to be distorted by the rush in such a manner that an abnormally *large* half-wave of current corresponds to an abnormally *small* half-wave of secondary E.M.F., and *vice versa.* These conclusions are fully borne out by the curves given in Fig. 6.

(*To be continued.*)

THE DECORATIVE USE OF GLOW LAMPS.*

The immense advantage which electric incandescent lighting possesses is, that it lends itself so readily to decorative purposes. In order that it may be employed in this sense to the best advantage, certain general guiding principles have to be held in view and followed. Unfortunately, this is not always the case, and the result is, that the effectiveness of the light, from the artistic point of view, is greatly diminished. The first principle which should be allowed to guide us in the production of an artistic effect by electric lighting is, that while a proper and sufficient illumination is thrown upon the surfaces to be illuminated, the source of light must be itself, as far as possible, concealed. The illuminating power of a light for the purpose of vision does not depend merely upon the candle-power of the lamp, but it depends upon the amount of light which is received by the eye from the surfaces from which it is reflected. The pupil of the eye is capable of being varied over wide limits, probably from about four square millimetres, or the 150th part of a square inch, to 70 square millimetres or the tenth part of a square inch. This expansion or contraction of the pupil of the eye is effected by muscles over which the will has no control, and it is termed in physiology a "reflex action." If the eye has been kept in darkness for some time, then the pupil becomes expanded to its greatest extent. Under these conditions, if the eye is opened, and especially if exposed to a bright light, this light falling on the retina causes an immediate muscular contraction of the pupil to be effected. It is very easy to see this adjusting process going on in the eye by shutting the eyes for a few minutes and then opening them in a bright light whilst a hand mirror is held before the face so as to examine the pupils of the eyes, the pupils will be seen to be rapidly contracting in area immediately the eyes are opened. Hence, if the eye is turned upon a brilliant line of light, the contraction of the pupil which immediately sets in imposes a limitation upon the amount of light which can enter the eye; and if the eye is turned immediately towards a dull badly illuminated surface, the pupil is not at once suddenly expanded again. One part, at any rate, of the injurious effect produced by trying to read or write in the twilight is due to the strain produced in the eyes by the muscular effort thus demanded in the eye. When, therefore, we enter a room in which there are a number of bright lights, such for instance as a room in which incandescent lamps are being employed, the filaments of which can be seen, the moment that the eye is turned upon these bright lines of light, muscular contraction of the pupil sets in, and on turning the eye away again to other less illuminated surfaces, the retina of the eye does not receive sufficient light to observe details. In common language, the eye is dazzled. There is a certain fascination about brilliant points or lines of light which captivates and attracts the eye even against the will. It will thus be seen that the presence of brilliant lines or points of light in a room has a tendency to keep the pupil of the eye in a state of partial contraction, which unfits it for obtaining the best visual effect when turned upon surfaces less illuminated. Some eyes are especially sensitive in this respect. If, however, the lamp globes are made of frosted glass, or in other ways protected so that the image of the incandescent filament cannot be directly thrown upon the retina, the actual visual effect may be increased in spite of the fact that such frosted globes or screens may cut off from 30 to 50 per cent. of the light. This is a common experience with everybody who tries to read or write in the neighbourhood of a brilliant incandescent lamp. By covering the globe with tissue paper or a ground glass or a porcelain shade, although a diminution to a very large extent is produced in the total light actually distributed from the lamp, yet, nevertheless, we are able to see better and more comfortab'y by it. The process, however, which is commonly adopted of cutting off a large proportion of the light by a semi-opaque globe is a wasteful one, because there can be no object in making light merely to absorb it.

The proper method is to so place the incandescent lamp that no light from the filament can directly enter the eye; but that all the light sent out from the filament shall be reflected to the eye from the objects to be seen, such as the walls of the room and the various objects in the room, and that the light shall reach the eye only after reflection from their surfaces. Bare or uncovered lamps, and especially if suspended half way down a room or on a level with, or a little above the eye, are a crude and exceedingly disagreeable method of illumination. In all cases where incandescent lighting is carried out by those who understand the proper methods of using it, so as to produce the best artistic effects, the guiding principle is followed of so placing the lamps that the whole of the light emitted from them only reaches the eye after reflection from surrounding objects. This result can be attained in a variety of ways. The lamps may be placed in shades so as to throw the light upwards upon the ceiling of the room or upon the walls, from which surfaces it is ultimately reflected down on to the objects in the room. Wherever highly decorated and light ceilings exist in a room to be lit, this is a very effective method of distributing the light. It is always possible to arrange glow lamps, protecting them by metallic or other ornamental shields, so as to obtain this desired effect. A natural shell, properly supported, forms a

* From a forthcoming work on "Electric Lamps and Electric Lighting," by Dr. J. A. Fleming, to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

Digitized by Google

very effective screen and reflecting surface. The white pearly interior of the shell acts as a reflecting surface, and if the shell is very slightly translucent, then a pleasing effect is produced by the small and diffused light which passes through.

The second important principle of decorative electric lighting is to distribute the light properly and to prevent the concentration of light in large masses, thereby avoiding the production of harsh shadows. Everyone is familiar with the exceedingly disagreeable effect which is produced by sharp and strong shadows. A soft gradation of light and shade is essential to the production of an artistic effect in a room. The inartistic productions of many amateur photographers, especially in the region of portraiture, are much more due to the fact that they have not the means at their disposal for producing the right effects of light and shade on their subjects, than to any defects in their photographic manipulation. Any concentration of the light in large masses, in public or private rooms, and especially when thrown downwards, invariably produces disagreeable shadows upon the face; and, therefore, in places like ball-rooms or drawing-rooms no such process of employing downwardly-suspended incandescent lamps should ever be permitted if it is desired to obtain the best results. All artists know the immense importance of obtaining proper lighting by diffused light, and the northern aspect which they invariably select for their studios is determined by this consideration. It is essential that the light should be so distributed in small units, in order that there shall be no sharp shadows cast upon any object. A simple test for the effectiveness of the distribution of light in any room may be obtained as follows: Take a white card or a sheet of white writing paper and hold it horizontally about the level of the eyes, then hold a pencil or other small rod vertically on the card, and note if any marked shadow of the pencil is thrown in any direction: if it is, then the light is insufficiently diffused, and the lamps ought to be re-arranged. The best effects as to distribution of light are generally obtained by the employment of 5 candle-power lamps. These glow lamps are constructed with bulbs of semi-opaque glass having the shape of a candle flame. These candle lamps are carried on the extremity of an artificial porcelain candle, so as to resemble in some degree an ordinary wax candle alight. These lamps are then arranged in groups on chandeliers or brackets, being protected in many cases from direct visibility by plain or ornamental shades. A third great guiding principle of artistic lighting is to proportion the light to the nature of the surfaces from which it is reflected. We require light in our living rooms to see the pictures, decorations, objects, and, above all, to see one another; and we can only see these objects by the light which they reflect back to the eye. The aim should therefore be to have sufficient but not excessive incident light. It should be borne in mind that the different surfaces with which the walls of rooms are covered have very different reflective powers. Dull walls absorb eighty per cent. of the light falling on them, and reflect only about twenty per cent. of the light; this is the case, for instance, with walls covered with dark oak panelling or dull-coloured paint or paper. Ordinary light tints of paper or paint may reflect from forty to sixty per cent.; clean white surfaces, such as white painted and varnished wood or plaster, may reflect as much as eighty per cent., and mirrors from eighty to ninety per cent.

The following figures have been given by Dr. Sumpner for the reflecting power of various surfaces:—

Table *of Reflecting Powers of Various Surfaces.*

White blotting paper	82 per cent.	Plane deal (clean)	40–50 per cent.
Ordinary foolscap ...	70 „ „	Plane deal (dirty) ...	20 „ „
Newspapers.........	50–70 „ „	Yellow painted wall (dirty)	20 „ „
Yellow wall paper ...	40 „ „	Yellow painted wall (clean)	40 „ „
Blue paper	25 „ „	Black cloth	1·2 „ „
Dark brown paper ...	13 „ „	Black velvet	·4 „ „
Deep chocolate paper	4 „ „		

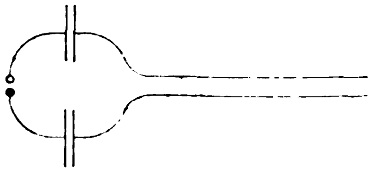
Everyone is familiar with the way in which the laying of a white table-cloth brightens up a dark dining room, or in which the substitution of white for dark curtains lightens up a room. The reason for this is obvious from the above table. Hence, rooms with dark oil paintings, dark woodwork, hangings, curtains, or portières require relatively much more illumination per square foot than rooms with very light decorations, water-colour paintings, mirrors, &c. Experience has shown that in a room of the latter description an illumination is required which is equal to an expenditure in the lamp of about ¾ or 1 watt per square foot of floor surface, on the assumption that the lamps are placed, on an average, about 8 or 9 feet above the floor. A room of the former description, such as a picture gallery with dark oak walls, may require from 2 to 3 watts per square foot of floor surface. These figures, however, cannot be taken too absolutely. Experience is the only guide as to the amount of light to be placed in a room. As a broad general rule, 100 square feet of floor surface will be barely illuminated by one 16-c.p. lamp placed about 8 feet above the floor. It will be well illuminated by two such lamps placed 8 feet above the floor, and brilliantly illuminated by four such lamps. In other words, one 16-c.p. lamp per 100 square feet of floor surface is hardly sufficient, one 16-c.p. lamp per 50 square feet of floor surface is fairly good, and one for every 25 square feet of floor surface is brilliant. These figures are given on the assumption that the lamp is placed about 8 feet above the floor, and that the floor surface is fairly reflective. The lighting of pictures is a very special study, and can only be properly undertaken by those who have given considerable attention to the method of placing and using incandescent lamps. The mere illumination of a room by a number of lamps hung head downwards by cord pendants from the ceiling, a method which is not unusually adopted, is the most crude and imperfect method of applying the electric light, and ought never to be permitted in any cases where the smallest decorative effect is really desired.

FURTHER NOTES TO THE LECTURE ON THE WORK OF HERTZ.

BY DR. OLIVER LODGE.

It may be well to explain that in my Royal Institution lecture I made no reference to the transmission of waves along *wires*. I regard the transmission of waves in *free space* as the special discovery of Hertz. Their transmission along wires is a much older thing, Von Bezold saw them in 1870, and I myself got quantitative evidence of nodes and loops in wires when working with Mr. Chattock in the session 1887-8 (*see*, for instance, reports of the Bath meeting of the British Association, 1888), and I exhibited them some time afterwards to the Physical Society.

It may be worth mentioning that the arrangement frequently referred to in Germany by the name of Lecher (viz., that shown in the figure), and on which a great number of experiments



have been made, is nothing but a pair of Leyden jars with long wires leading from their outer coats. The use of air dielectric instead of glass permits the capacity to be adjusted, and also readily enables the capacity to be small, and the frequency, therefore, high; but otherwise the arrangement is the same in principle as had frequently been used by myself in the series of experiments called "the recoil kick." For these and other reasons no reference has been made in my lecture to the excellent work done on wires by Sarasin and De la Rive; nor to work done by Lecher, Rubens, Arons, Paalzow, Ritter, Blondlot, Curie, D. E. Jones, Yule, Barton, and other experimenters.

CORRESPONDENCE.

DIRECT-READING MAGNETIC APPARATUS.

[*Translation.*]

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the remarks on my apparatus for the determination of the magnetic qualities of iron which you make in the issue for July 6, 1894, of your valuable paper, and which I have read with much interest, the concluding sentence is as follows: "Would it not simplify matters to make it a torsional zero-reading instrument, and thus do away with the compensation which would be necessary for the magnetising effect of the swinging coil itself?" &c.

I may remark in this connection, that unfortunately a mistake occurs here on the part of your esteemed correspondent, in that he assumes that the compensating windings are used to neutralise the effect of the moveable coil. This is not the case; the magnetic effect of the movable coil is practically nothing. The compensating winding is intended to neutralise the magnetic effect of the fixed magnetising coil on the yoke, for otherwise one would measure B + H with the instrument. Even if for wrought iron there is no great difference between B + H and B, yet for less permeable kinds of iron this difference would become very large; and even for better kinds of iron it must be taken into consideration, since the measurement does not take place at the test piece but at the yoke, and one would therefore be compelled to subtract the readings taken with no test piece in the instrument from those obtained with the test piece in place. The compensating winding enables the instrument to do this automatically when the measurement is made, so that all kinds of iron give directly comparable results in the instrument.

Thus a torsional apparatus would also require a compensating coil, and would lack the universally-acknowledged advantages of a direct-reading instrument.—Yours, &c.,

Berlin, July 17, 1894. (Signed) DR. ADOLF KOEPSEL.

VACUUM TUBE EXPERIMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have been continuing the series of experiments on vacuum tubes which I have undertaken.

A remarkable result has been obtained which may interest your readers, and I do not think that it has been found already.

A tube was fitted with two "Hertz grids" midway in its length, then exhausted. The grids were "crossed." Under these conditions the current should not traverse the tube end to end. But since residual matter enters into the phenomenon of the bands formed in vacuum tubes, any prediction might be falsified. It might be thought that partial bands would appear in the tube on each side of the grids (which were close to one another) since the current employed was an alternate one. The actual result was that under no conditions could the tube be made to show the *faintest* sign of light. During the next few months I shall be making several further experiments with "grids" at various angles, and other experiments connected with the subject, which will be published in due course.—Yours, &c., DAVID SALOMONS.

July 19, 1894.

Proposals for the Paris Exhibition, 1900.—Thirty-six projects for what is called the Clou, or main attraction, of the Paris Exhibition for 1900 have been sent in to the special subcommittee. The well-known engineer, M. Armengaud Jeune, proposes the offering of handsome prizes for solutions of the three following elementary problems, transmission of sight to a distance, chromo-photography on paper, electric lighting without focus by cold light with the aid of electric undulations of great frequency. M. Trouvé has not quite such lofty ideas, nevertheless even he advocates nothing less than a luminous cascade falling from the upper platform of the Eiffel Tower and also a luminous fountain rising to the same height.

LEGAL INTELLIGENCE.

Re Woodhouse and Rawson United (Limited).

FRIDAY, JULY 20TH.

Sir Rawson Rawson again went into the box, and his examination was continued by the Official Receiver. Sir RAWSON said he wished to assure the Court that he had every disposition to assist it and the Official Receiver, but at four-score and two the memory was liable to fail. Statements made by himself in a speech to shareholders to the effect that the profits of the preceding year were not accidental or casual, but would be repeated; being put to the witness, he said in 1891 they had the prospect of a very valuable concession, and of considerable profits arising therefrom. He did not suggest that the Okonite Company, the Kensington Stores, and the other concerns would again yield large sums, but he did anticipate that there would be other business of a similar character. He first became aware of the connection of his son, the Managing Director, with the Phœnix Trust Company just before the meeting, at which the latter explained the circumstances of his joining the Company, and at which he undertook to draw up a report upon the subject. Witness did not know until some time later that Baron Grant was connected with the Phœnix Trust. A letter came some time in 1891 signed by Baron Grant, and this it was which led to their hearing of his connection with the Company. Witness knew nothing whatever of the National Financial Corporation, and was not aware that his son had any connection with the concern. He was not aware that Baron Grant was consulted in any way about the formation of the United Company, but knew that there was a private telephone wire between the offices of the Company and Baron Grant's offices. Baron Grant was intimately concerned in the Elmore Companies, and he knew his son was using his utmost endeavours to make those companies prosperous. He could not say whether the other Directors were aware of this telephone connection.

Mr. JENKINS wanted to know whether it had ever been proved to be a fraud to speak to Baron Grant.

The REGISTRAR said certain names which were notorious were being introduced, and he supposed the suggestion was that there was a certain amount of suspicion in the connection; he did not think, however, there was any need to bring in those names.

The OFFICIAL RECEIVER said his only reason for referring to Baron Grant was that Mr. Pope had referred to him as a man to be associated with whom was not likely to add to the prestige of the Company.

Mr. JENKINS said it was not quite fair to put this upon Mr. Pope. All that gentleman had done was to point to the fact that a resolution was passed.

Mr. H. G. RAWSON said the way in which the matter of the telephone wire had been put by the Official Receiver was misleading. As a matter of fact, the connection was with the Phœnix Trust Company's offices.

Mr. F. L. RAWSON: And the Phœnix Trust Company paid for that telephone. We did not.

The WITNESS was then examined by Mr. F. L. Rawson, and said he did not recollect being informed when the Phœnix Trust Company was first formed that Baron Grant, amongst others, was to be connected with it. With regard to the anticipated profits of the last six months of 1890, the French Elmore Company was brought out in that period with considerable profit to the United Company. The Austrian Company was brought out about October, 1890, and the profits from that came into the succeeding year. They also received a commission on the sale of the German patents. Mr. North, the business manager, told him that they should make a profit of from £6,000 to £8,000 in that year at the Kidsgrove works. In 1891 they had a call upon about 2,500 Ward Car shares. But for the legal restrictions upon the running of the Ward electrical cars, shares would have been very valuable; as it was they had to have a man with a red flag in front of the cars. The police authorities were satisfied with the cars, but an Act of Parliament was necessary to enable them to run them. Witness did not remember the exact figures mentioned, but he understood there would have been a considerable economy in the cost of running these cars as compared with horse-drawn vehicles. With regard to the value of the Epstein shares, the opinion of the best patent agents was taken as to the value of the patents, and also the opinion of three or four leading counsel as to their validity, and upon this they based their valuation of their shares. When the time came for fixing the valuation of the Phœnix Trust shares, they obtained from the managing director a statement of the items forming the valuation. Some question arose about one or two points, and they were referred back, and there was a reduction in the valuation. They took a great deal of pains to satisfy themselves in 1891 of the value of the Elmore shares, as well as of the shares of all the other concerns in which they were interested. All the Directors felt that Mr. Rawson (the Managing Director) had made great personal sacrifices to support the Company, sacrifices of a very unusual character; and, he might say, they reproached themselves for allowing him to do so. As to the reason why the arrangement was made for the repayment of his debt in debenture stock, witness's recollection was that at first it was supposed that his (Mr. Rawson's) interest in Woodhouse and Rawson (Limited) would be liquidated in cash; but as the guarantee fund was largely repaid to the Limited Company in debentures, it was thought only fair that Mr. Rawson should be permitted to repay his debt to the United Company in the same substance.

By Mr. Pilling: WITNESS never heard of or saw a balance-sheet of the Epstein Company which showed a loss of £5,000 for the first year of working. He was not aware, as a matter of recollection, that the founders' shares of the Phœnix Trust Company, which they had acquired for £25, were valued in the books at £15,000; but if the figures were in the books he would accept them. Witness could not say how many shares the United Company held in the Phœnix Trust, and did not know whether Mr.

Digitized by Google

Pilling's suggestion of four was accurate or not. Mr. Pilling suggested that the original arrangement with regard to the loan made to Mr. Rawson was that he was handed a cheque with which to buy shares, and that when those shares were sold the proceeds should be handed to the Company. Witness would not altogether agree to the proposition; but the purchase was made in the interests of the Company, and not in Mr. Rawson's own interests. If the shares had been sold no doubt the money would have been repaid in cash. There were but two members of witness's family besides himself concerned in the administration—Mr. Stepney Rawson, the electrician of the Company, and Mr. Frederick Rawson, the managing Director. These had both been connected with the Limited Company, with which witness had nothing to do, and when the United Company took over the business of the Limited it took over his sons as well. Mr. Henry Rawson, who was a barrister, had attended meetings of the Board, partly because Mr. Pope found himself unable to attend regularly, and partly because witness himself needed assistance. For these attendances the fees paid to him were settled by Mr. Pope. Mr. Henry Rawson upon many occasions sacrificed his professional business in order to attend to the affairs of the Company.

By Mr. H. G. Rawson: When asked to join the Board of the United Company he looked into the documents connected with its formation, and satisfied himself that the prospectus was supported by those documents. Upon the last day that Sir Albert Cappell attended at Queen Victoria-street witness followed him into the corridor when he was leaving, and put to him the question as to whether there was in his mind any reason beyond insufficiency of the capital subscribed which would entitle him (witness) to refuse to become a Director if asked, and Sir Albert Cappell said, "No, the Company has an excellent business." The amount of capital which the Directors who retired thought should have been subscribed was reached the following week. Witness knew Sir John Coode well, and during a conversation subsequent to his retirement, Sir John said the Company had a very good business if well managed. Mr. North was specially engaged to take charge of the industrial business. He was sent to Kidsgrove to report on the works there, and his report was to the effect that the works, with a moderate expenditure in obtaining improved plant and buildings, would yield to the Company a profit of £6,000 or £8,000 a year. Witness's idea regarding those works was that they were in bad condition, but might be made most suitable for their purposes; therefore they paid a moderate sum for them. The explanation of the loss on the first year's working at Kidsgrove was that contracts had been accepted by the vendors which they were unable to carry out, and which the United Company were unable to carry out when they acquired the business. They had some difficulty in getting a suitable manager, but they had every confidence in Mr. Owen, the present manager, and anticipated successful working at Kidsgrove after his appointment. It certainly was not the fact that the Directors gave but little attention to the industrial business; on the contrary, they did their utmost to develop the industrial business. The document put in was a balance-sheet prepared by the Company's accountant at witness's request in 1891, and it showed a profit of £11,000 on the industrial business; this was the analysis of the accounts which witness sent to Lord Aberdare. The Directors did not desire to divulge the sources of their income to the public; but there was no attempt whatever to keep the information from the shareholders. The Board gave careful consideration to Mr. Pixley's suggestions, and had no reason to suppose that he was not ultimately satisfied with the course taken, or with the explanations offered on all the points he raised.

Mr. F. L. RAWSON, Managing Director of the Company, was next called; and, examined by the Official Receiver, said he was never a considerable holder of shares in the Limited Company. The Directors had always desired that the vendors (him-elf and Mr. Woodhouse) should not acquire a preponderating influence, and he did not think that their joint interest amounted to more than from £10,000 to £16,000. He could not say now whether he had any interest in shares in the Manufacturing Company which were in Mr. Woodhouse's name. He was the holder of 261 shares in the Supply Company, and 108 shares in the Contract Company, but he believed he held the latter for the Limited Company. The partnership between Mr. Woodhouse and himself started in 1881, and the Manufacturing and Supply Companies were formed about 1886 or 1887. At this latter period the partnership was certainly solvent. Mr. Woodhouse died about a month after the formation of Woodhouse and Rawson (Limited) in 1887. He knew Mr. Harper, who was an accountant in his employ, but was not the chief accountant of the firm. Mr. Harper's statements that the partnership and the subsidiary companies were insolvent, that there were large mortgages on the Cadby Hall works, that the mortgagees were pressing, and that the Manufacturing Company was started to a great extent to relieve the mortgage, were all absolutely untrue. These statements were made in the course of the examination of a man who had brought an action against him (witness), and without any cross-examination. As a matter of fact they never had the Cadby Hall property at that time, and there were no mortgages upon it. There was a sum of money lent to them by Mr. Philip Rawson when they started business. They borrowed money on the business, and on securities; and where money was so borrowed, it usually happened that the lender would from time to time ask for his money back. The best test as to their being in difficulties for money, he thought, was the interest they had to pay, and he did not think they had ever paid more than 6 per cent. in their lives. The private books of the partnership were kept by Mr. Ward, and not by Harper, and the latter, witness was perfectly certain, could not have seen them at that date. Witness could not produce any accounts relating to the partnership. He was quite sure the partnership was solvent, because Messrs. Spain, the accountants, went through the books specially, and their report was so thoroughly satisfactory that, upon the strength of it they were able to borrow £2,000 at 5 per cent. This was just before the formation of Woodhouse and Rawson (Limited), in 1887. The shares held by the partnership in the Manufacturing and Supply Companies were taken account of by Messrs. Spain and included, witness thought, at cost price. Just about that date they had lost a considerable amount of money through an action with the Edison-Swan Company, and it was the shortness of capital in consequence that led to the formation of the Limited Company. Witness could suggest no grounds for Harper's statements beyond the fact that he had brought an action against him and, he supposed, was not particularly well-disposed towards him. About 1884 or 1885, when the electric lighting companies were being brought out, they could have sold their business at a very large profit indeed; they had an offer made to them of many tens of thousands of pounds, and they refused it.

The OFFICIAL RECEIVER: Are you aware that a balance-sheet of the Manufacturing Company, got out by Mr. Champneys, for the year ended June 30, 1889, and that, taking the goodwill of the business as being worth £37,265, there was a deficiency of £44,000?—I am aware of it, because you have stated it. But that does not take in the value of the patents.

You are aware that at the time there was an accumulated debit on the profit and loss account of £34,936?—Mr. Champney's figures make it so. Of course, that did not include anything for the arrangement made with the British Company for the manufacture of the lamps, and did not include anything for the patents.

Woodhouse and Rawson (Limited) in 1889 were creditors for about £35,000?—Possibly.

And they held some 26,000 shares?—Yes. WITNESS did not think the figures showing a deficiency of £70,000 at the time when the United Company purchased the business were correct; but there was a large deficiency, and he had always stated that Woodhouse and Rawson (Limited) squeezed the Manufacturing Company, and that the proper price was not paid for that business.

The OFFICIAL RECEIVER read the special report of Messrs. Chandler and Pixley, the auditors, on the accounts of the Supply Company to September 30, 1887, in which it was stated that there was a loss on the whole business of £2,923, and asked witness if he thought that was a satisfactory report.

WITNESS: I think it is satisfactory because it shows how carefully Messrs. Chandler and Pixley went into the affairs of the Company.

The OFFICIAL RECEIVER: I am not asking you about that. Is that not a very unsatisfactory report?—It was rather better than we expected. The previous year we had made a good profit. Then we had our lamp business stopped, and I have no doubt that that large loss is caused by our having to write down a large amount of stock to a merely nominal value.

At this stage the proceedings were adjourned until Tuesday.

TUESDAY, JULY 24TH.

The OFFICIAL RECEIVER said he had not understood his Honour's remarks at the previous hearing with regard to the mention of well-known names to mean that he was not to go into the question of the promotion of the Company. He had reason to suppose, from the correspondence, that Baron Grant at all events was consulted with reference to the Company.

The REGISTRAR said he had not the slightest wish to check the Official Receiver in any way in regard to anything he thought it particularly necessary to bring out.

Mr. F. L. RAWSON was again sworn, and replying to the Official Receiver, stated that his explanation of the report of Messrs. Chandler and Pixley in 1888 as to the payment of a dividend by the Supply Company amounting to £501, notwithstanding that heavy losses had been sustained, was that an interim dividend was paid in consequence of their having made a special profit in connection with the Welsbach Company. The result of the operations of the Company was that there was a loss during the year in consequence of their being beaten in the Edison-Swan action. It turned out that they were unable to sell their lamps, and therefore they had to write down the value of the lamps, which brought out a loss instead of a profit. The position of the Company improved in the next year, for, although they were unable to do much with lamps, they worked up a business in other goods. He considered that the position of the Supply Company in 1889 was very good. The Woodhouse and Rawson partnership guaranteed the whole of the book debts to the Limited Company; it was not true that £17,000 was still unpaid under that guarantee. The minute of a meeting of the Liquidators of the Limited Company, held in July, 189', was incorrect when it stated that that amount was still due. The debt of the Manufacturing Company was not paid quite in full.

The OFFICIAL RECEIVER: May I take it that the debt was not discharged?—No; the debt was discharged, because more than the amount we guaranteed was paid by the Manufacturing Company to Woodhouse and Rawson (Limited), and it was later advances made by Woodhouse and Rawson (Limited) to the Manufacturing Company, after the date of the formation of the United, that were unpaid. I did not guarantee those. The Liquidators made absolutely certain that they got everything from the firm of Woodhouse and Rawson that they possibly could. They raised all the points they could.

Did you complain of the incorrectness of this minute?—Not at that date. I probably mentioned the matter at the following meeting.

What do you suggest the Limited received of the large amount due from the Manufacturing Company?—I suggest they received the whole of that, chiefly in shares; but partly in cash.

Mr. Hoster admits that the debt was not paid in full, and I thought you had admitted it.—I admitted that the money was due at that date, but part of that was liquidated after the formation of the United, chiefly by the fact that the United did not take over the Manufacturing Company's business for some considerable time.

You say that on the formation of the United Company the guarantee of the Woodhouse and Rawson partnership ceased?—So the solicitors stated. My recollection is that Mr. Hoster took one view, and the rest

Digitized by Google

of the Directors took the same view as myself. Mr. Hoster insisted upon going to the solicitors to see if they could get anything more out of me, and the solicitors advised that they could not.

As regards the Contract and Maintenance Company, are you aware that the accounts made up to December 31, 1888, in which the goodwill is taken at £5,000 as an asset, showed a loss of £3,144 ?—I am not aware of the precise figures ; I should have estimated the loss at about £1,500 or £2,000.

In June, 1889, the loss appears in the accounts of the auditors, a copy of which has been furnished to me, as being £3,450 ?—That shows an improvement. That is a loss of about £300 in seven months. The loss steadily decreased until in the second year of the United it was turned into a profit. All businesses of that nature must commence with a loss.

The Company began in 1887. Up to June 30th of that year the loss was £1,977 ; in the half-year ending December 31st that is increased to £2,482 ; in the next six months it is increased to £3,024 ; then to £3,144 in the next six months ; and on June 30, 1889, it stood at £3,435. That is a steady loss right throughout ?—A steadily diminishing loss right throughout.

Is that not a steady loss throughout ?—No, it is not.

Is there a single half-year's account which does not show a loss ?—No. The reason of that is that all the expenses of developing go into profit and loss. We were entitled to put those sums to a special fund. The business was steadily improving all the time.

You take your goodwill throughout here as a credit asset of £5,000 ?—Yes. That goodwill was steadily improving all through that period.

Can you seriously suggest that a business steadily losing throughout can have a goodwill ?—Certainly. Anyone who knows anything about these matters knows that losses, when they are steadily diminishing, are likely to turn to profits afterwards. The goodwill was the goodwill of Woodhouse and Rawson for contract business in the North of England and in connection with the Crossley Telephone Company, which was one of the most successful companies of the time. The principal man in that company was Louis John Crossley, a well-known electrical engineer, who was also a Director of the London and North-Western Railway, and his goodwill in a business of that sort was very valuable in itself. We had a contract for lighting the offices of the London and North-Western Railway, for lighting trains, and so on, which we should not have got but for his connection.

As regards the formation of the United Company, who was your financial adviser ? Who assisted you throughout ?—Eventually Mr. Budd, of Messrs. Budd and Johnson, solicitors ; in the early days Baron Grant advised me.

Can you give me the date when Baron Grant advised you ?—In the beginning or middle of 1888. I heard Baron Grant was forming a Company for taking over the Hammersmith Electric Lighting Act and combining certain businesses with it, and I went to see if I could get the contract for the works. That was my first acquaintance with him. We had negotiations, which resulted in my getting the contract. At that time I was negotiating the combination of the Manufacturing Company with the other businesses, and after some little time Baron Grant asked whether we would combine with the businesses he had in hand.

Then did not Baron Grant's assistance continue right up to the formation of the Company ?—I cannot say. I do not think he had very much to do at the end when Sir John Coode and Sir Albert Cappell resigned. But I took his advice during that year, at one time very often. But before I went to Baron Grant I went to our solicitor's, a man I consider one of the ablest solicitors in the City, and to our bankers, and explained fully to them the circumstances, and asked if they saw any objection to my consulting Baron Grant on financial points. They said there was not the slightest objection, and that he was a very able man.

All throughout that you were acting in the interests of the vendor ?—Yes, at that time. Baron Grant, I may say, was just as particular as the new Directors with regard to being satisfied on all points.

I do not wish to make the least suggestion that Baron Grant was not the best adviser possible, or that he did not give you the best advice. All I wish to know is, who were your financial advisers ?—He was most particular, and wanted everything explained to him about points he might have heard of elsewhere. I gave him full information about everything he asked me.

I see you were consulting him in September, 1889, and you ask him, "Do you think it worth taking any notice of ?" Evidently something about the Limited ?—Yes ; what I consulted him about was articles appearing in the Press. Baron Grant's advice in every case, so far as I recollect, was to take absolutely no notice of the Press, not to write letters contradicting, or explaining any statement. No letter, therefore, was ever written to the papers by the Company except upon purely technical matters.

Who drafted the prospectus ?—I did.

The REGISTRAR asked if Mr. Rawson wished to state anything further about Baron Grant.

WITNESS : Originally, when the amalgamation was proposed between the companies he had in hand and the companies that I was going to amalgamate, he made terms for handing over the Hammersmith Electric Lighting Act My recollection is that he was to receive £15,000. As time went on the new Directors went very carefully into the businesses, and ultimately they would have nothing to do with the Hammersmith Electric Lighting Act nor with the businesses that he had proposed to amalgamate. Baron Grant then claimed from us, Woodhouse and Rawson (Limited), that he ought to have some compensation, because he had lost his chance of bringing out those companies in the way he was going to do. Prospectuses had been prepared, and he had several directors for the companies he proposed to bring out. Then what I arranged with him was this, that we should pay him a fee for simply consulting him, and the fee ultimately was paid. I remember he objected to the amount of the fee, and said he had been very badly treated by Woodhouse and Rawson (Limited), and I paid him something myself. The amount he received from the Limited was somewhere round about £5,000.

The REGISTRAR : Have you any objection to saying how much you paid him ? I do not press the question.—I gave him a certain percentage upon certain profits I was going to have. Ultimately he got nothing. The maximum he could have had was £5,000, or possibly £7,000. I may state that that is approximately about the fee which is usually paid for work of this description.

The OFFICIAL RECEIVER : Mr. Rawson is not a specialist.

WITNESS : I am a specialist. I was myself offered £5,000 to act in a consultative capacity for an industrial concern recently brought out.

The REGISTRAR : Then Baron Grant only got £5,000 and this promise ?—£5,000 and the promise, from which he got nothing.

He had no interest in Woodhouse and Rawson ?—No ; not in any of the Companies. Witness added that he was afraid he had given a wrong impression in mentioning Baron Grant's name in connection with the arrangement. The arrangement was made with the National Financial Corporation.

The OFFICIAL RECEIVER : The National Financial Corporation was practically Baron Grant, was it not ?—I did not know that until you told me about nine months ago. He was the working man in it.

As regards the Phœnix Trust, I think Baron Grant and the National Financial Corporation and yourself practically constituted the Company, except for any interest the United Company had in it ?—And some small shareholders.

They are very small shareholders. Were the arrangements with the Phœnix Trust entered into in any way in consideration of Baron Grant's services in connection with the formation of the Limited Company ?—No, certainly not.

Baron Grant did not undertake any risk ? He was merely a friendly adviser ?—No risk at all.

So that any sums he did receive were simply in consideration of his friendly advice ?—Not friendly advice. Advising in that way was his business.

Now, as regards the prospectus of the United, did you consult him as regards that ?—Yes.

As regards this paragraph as to the profits of the Limited for the year ending June 30, 1888, stating that they were, as shown by the audited balance-sheet, £21,440, did you first desire that Mr. Pixley should allow his name to appear as certifying the accounts ?—Yes, we wanted him to give a certificate, but he objected.

On what grounds ?—On the ground that it was not his place to value the shares that were held by Woodhouse and Rawson (Limited). That lay with the Directors, and, therefore, he could not give a certificate with regard to the £75,000 for the following year ; his objection was that it was an estimate, and he could have nothing to with an estimate.

Mr. Pixley's view was that no one would be in a position to judge of the value of the certificate without reading the report ?—Unquestionably he says that. I do not think he really considered his answer. My reason for saying that is that I discussed that matter with him. I asked him if that was a fair statement to put in the prospectus, and he said it was, and signed the prospectus.

The REGISTRAR : What do you mean by signing the prospectus ?—I took over the draft of the prospectus the Directors were considering, and got him to put his own signature to it. I then took it back to the Directors. They also went into the question of whether it was a proper thing to put in.

Which of them ?—All of them on the Board at that time. It is very difficult to say who they were now.

Did Lord Aberdare consider that ?—It is difficult to say. I am certain that Mr. Whateley considered that most carefully.

Did Mr. Whateley have this report of 1889 on the £21,440 profits before him ?—Mr. Whateley was very very careful about all the details. I am not certain one way or the other about Lord Aberdare. I am certain about Sir John Coode, Sir Albert Cappell, and Colonel Howard Vincent.

Do you say they studied this report of Mr. Pixley ?—Over and over again. They not only did it, but they cross-examined Mr. Pixley himself upon it. They also had Sir John Stokes, and I think Mr. Hoster, before them, and went fully into those reports. I cannot say as to Mr. Philip Rawson.

You know the paragraph at the end of this report ?—"The accounts are in accordance with the books of the Company, but it is obviously impossible for us to be responsible for the net profits, having regard to the nature of the assets and the Company's interest in many trading concerns not yet fully developed and without Stock Exchange quotations of their shares."—It was absolutely impossible for anyone to be responsible.

Quite so ; but was not that a material paragraph to be brought before anyone investing in the United Company ?—No. Auditors are commonly in the habit of giving their certificate qualifying it with a report as Mr. Pixley did. Mr. Pixley has the reputation of being one of the most particular auditors there are, and he always qualifies his certificate if he can.

My recollection of his evidence is that it was a very unusual course for him to adopt ?—It is an unusual course, and it might ruin a company with a business of this nature.

Then as regards the statements in the prospectus as to the various businesses taken over. Except the paragraph saying that owing to the reputation acquired by the Company and its experienced electrical staff, they were often consulted by patentees as to the best means of turning their inventions to account, can you point to any information to the investor that the Company was to go into a considerable promotion business ?—Not a considerable promotion business, but it says the business was not confined to any particular branch, but was especially engaged in many directions unknown to the public. The endeavour was to show that we were

Digitized by Google

going in for the business of dealing in patents, and patentees reading that would know what it meant.

The REGISTRAR: That is not the point, what a patentee would understand. An uninstructed person would assume that the Company had a large business in giving advice, and not in promotion.—That was not my view after constructing it.

Mr. JENKINS: It goes on to say: "And from this source considerable profit has been derived." Considerable profit could not be derived from advising.

The REGISTRAR was of opinion that members of the Bar derived profits from their practice of giving advice.

Mr. JENKINS dissented from the suggestion that "considerable profits" were so derived.

WITNESS: What I meant was the financial business of buying patents and selling them to companies brought out. Anyone knowing anything about patents knows that you have to form a company to work a patent. You cannot get them taken up by existing firms.

The OFFICIAL RECEIVER: I asked if there was any other paragraph you could point to beside that.—I do not suppose there is. But as showing the probable effect upon the public mind I may say that it was commented upon in the Press at the time that we were going in for this business. The papers said it was abundantly clear the Company was going to do that class of business, and they thought it was a mistake.

You contemplated this business?—Yes, because we had these patents that we expected to sell for a large sum.

There is a paragraph here saying that valuations had been made by competent experts, and the amount placed on these patents had been the guide in fixing the purchase money?—That is the case.

You have read Mr. Edmunds's valuations, addressed to the Directors of the Electrical Union. Can you tell me what you understood to be the figure at which Mr. Edmunds has valued these patents?—He valued the patents held by the Manufacturing Company at £37,265; the lamp patents at £60,000; and the other patents, including the interest in the foreign Elmore patents, the Elmore zinc patents, and a number of others, at £125,000; altogether, just over £220,000. The way we got down to £159,000 in the Directors' statement was this: In between the date of his valuation, April 12th, and the date when the United Company came out, the end of July, the interest in the foreign Elmore patents had been sold to the foreign Elmore Company. The Directors took the amount it had been sold for, and deducted it from the total valuation, and so brought out £159,000 as the value of what remained.

Did the Directors consult Mr. Edmunds at all about the value he put on the Elmore patents?—No; he was in America, or he would have been consulted.

You see by his examination that Mr. Edmunds says his idea was that he had valued the patents at something like £159,000?—Yes. Evidently he had forgotten the circumstances.

It is impossible to gather from the valuation what the value placed by Mr. Edmunds really was?—WITNESS: I had to get him to explain it to me.

I asked Mr. Edmunds what was the amount, and he had great difficulty in finding it out, and finally he acquiesced in the figure £159,000.—WITNESS: Mr. Edmunds was very very ill for months after that. He could not explain it to me when I saw him just before his examination. He had not the slightest recollection. When the valuation was made, and I first read it through, I told him I did not think he had got it clear. Then he explained it and I saw it, but I wanted him to put it clearer, and he refused, saying it was quite clear enough.

As regards the valuation of these patents, the information was supplied by you to him, was it not?—Yes, as is usual.

You employed Mr. Edmunds as representing the Limited Company?—No, I did not. I made it absolutely clear that his valuation was for the new company.

In his examination Mr. Edmunds says, "Possibly if I had been employed by the purchasers I might not have had that information from Mr. Rawson." From that I do not understand that Mr. Edmunds was clear that he was employed by anybody except the Vendors?—I think Mr. Edmunds could not recollect, and gave you a fencing answer. He could not say one way or the other. I told him distinctly it was made for the Directors, and it was addressed to them. He wanted 10 guineas if the valuation was used on the prospectus, and 50 guineas if only for the new Directors. The Limited paid him, but he was distinctly informed that the valuation was for the new Directors.

You told me early in your examination that when you consulted Baron Grant you were acting for the Limited Company. Did you depart, when you came to Mr. Edmunds, from that position?—No. I gave him the instructions as for the Directors of the United Company.

But there were no Directors in April, 1889?—Oh, yes. There were Directors in 1888—*in posse*. I cannot recollect who they were; but I sent a draft prospectus in October, 1888, to Mr. Baker, who was to have been a Director.

Seriously, do you suggest that the Directors of the United Company had anything to do with the valuation of Mr. Edmunds?—Oh, yes. There is not the slightest doubt about that at all.

But the Company was not formed until July, 1889?—There were Directors—proposed Directors—certainly in October, 1888, Directors who were looking into and investigating the affairs of the Company.

The REGISTRAR: Who were they?—I do not recollect. There were several people selling us businesses who all wanted to have a Director on the Board, and these went into the affairs of the Company. I do not want to mention names, because people do not like to have their names mentioned as having been proposed Directors of a Company when they did not actually become Directors.

The OFFICIAL RECEIVER: But I want to know. You must have had something in your mind.—WITNESS: What was in my mind was that I would have got out of that valuation if I could have avoided it, partly on account of my dread that the valuation might come out badly.

But you could not have floated your Company without a valuation?—Oh, yes; you do not usually value the patents in such a case.

I put it to you that you employed Mr. Edmunds to value the patents?—And I tell you that I certainly did not. I took every care, and made it clear that the valuation was on behalf of the new Directors.

The REGISTRAR: Did he not take your valuation and knock something off?—No. What happened was this. His headquarters were at Manchester, and he asked me if I would have the actual writing done. The heads of the report were made out in my office, and he took them away, and I recollect quite well that he came back and put in the amounts. I was quite surprised by some of those figures. It was not in my mind a satisfactory valuation. I wanted the valuation as soon as possible, and made my case as strong as possible, but he wanted documents to confirm my statements. If I had had any idea of this I would have refreshed Mr. Edmunds' memory when I saw him.

The OFFICIAL RECEIVER: As to the question of your interest in the Phœnix Trust I see there is a minute of September 3, 1890, stating that "the Managing Director again explained the circumstances in connection with the formation of the Phœnix Trust Company, and his joining the Board as a Director, and stated that he was going to make a report in writing to the Board, so that they might have a record in writing of the same." Will you tell me at which Board meeting this report was brought up?—At one of the meetings in September, 1890. I believe there is no record of the report in any of the minutes.

Mr. Philip Rawson said in his examination that he first learnt of your connection with the Phœnix Trust in January, 1892, and that he never saw the report, and did not recollect it. Can you point to any one of the Directors who were aware in September, 1890, of your connection with the Phœnix Trust?—Sir Rawson Rawson and Mr. Philip Rawson unquestionably were. In November, 1891, I stated to the Board that if they thought there was any objection to my having those shares in the Phœnix Company I would not only give them up, but also all the dividends I had received during the year. The Directors thought I was rather more entitled to them than before because they saw the amount of work that had fallen to me in forming the Phœnix Company.

On September 27, 1890, you wrote to Baron Grant that you had let your Directors know from time to time of the nature of your connection with the Phœnix Trust, and had made to them a report in writing, and had it entered in the minutes.—That proves exactly what I say.

But you say you sent in a written report and had it entered in the minutes.—There may have been a misunderstanding as to that, but there is reference to the Directors asking me to make a report in writing.

With the exception of Sir Rawson Rawson, can you point to any Director who has in his evidence admitted that he knew of your connection with the Phœnix Trust on or about that date of September, 1890?—No. Mr. Pope may not have known at that date, as he was often away from the meetings for some time.

Mr. H. G. RAWSON: If I had seen the relevancy of it I would have asked the question. At the present moment I am utterly in the dark as to its meaning.

The OFFICIAL RECEIVER: One of the Directors is making a profit unknown to the other Directors.

Mr. H. G. RAWSON and Mr. JENKINS both said this was the first suggestion of any such thing.

WITNESS said Baron Grant advised him to make the offer of which he had spoken to the Board.

After the luncheon interval,

Mr. H. G. RAWSON said he had had an opportunity of asking Sir Rawson Rawson what his recollection was as to the date when he first became aware of the Managing Director's connection with the Phœnix Trust Company. He (Mr. Rawson) would have asked him specifically if he had known the question was going to be raised. The question put by the Official Receiver was, "When did you know of the connection of Baron Grant with the Phœnix Trust Company," and as he considered the question irrelevant he did not give any attention to it. The other question, on the contrary, was excessively material; and, if his honour wished, Sir Rawson Rawson was prepared to go into the box and answer the question.

Sir RAWSON RAWSON was then sworn, and asked by Mr. H. G. RAWSON: When were you first aware of the connection of the Managing Director with the Phœnix Company and of his pecuniary interest in that Company?—Witness: Before it was actually formed, to the best of my recollection.

Can you speak as to the knowledge of the Board generally?—My recollection is that the Managing Director reported to the Board sometime in 1890 the difficulty he had in disposing of the Elmore shares in London. We were very anxious to realise the Elmore shares, and he reported to me the formation of this Company. I cannot say whether he reported to the Board before the Company was formed, but he certainly reported to me before that because he brought the Chairman of the Board to me. That was not Baron Grant. I cannot say who the Directors were who were present when the matter was discussed. My recollection is that the Managing Director explained everything fully, and that it was known what the consideration was he was to receive. There ought to have been a record of the report in the books, and he could not explain why there was not

The OFFICIAL RECEIVER: Was it explained to the Board that the Phœnix Trust Company was practically composed of Baron Grant and Mr. Rawson?—No; that was not so. To the best of my belief Baron Grant was not a Director at all. He may have been interested in it. I think I mentioned before that I think the attention of the Board was first called to his connection with the Company by a letter coming from the Phœnix Company, signed by Grant. I was surprised at it, and called the attention of the Managing Director to it.

Digitized by Google

Were you aware that out of the 4,078 shares issued 1,000 were held by Mr. F. L. Rawson, 1,000 by Mrs. F. L. Rawson, 1,000 by the National Financial Corporation, and 1,000 by Baron Albert Grant?—I know nothing about that.

Then how could your Managing Director have explained the circumstances in connection with the formation of the Phœnix Company? Was not that very material?—No, I think not. The Company was formed to help Woodhouse and Rawson United to dispose of the Elmore shares.

You stated in your examination on the last occasion that you were not aware that Baron Grant had *assisted* in any way in the formation of the Company?—I did state that. I have learnt it to-day for the first time.

Was it explained to the Board at the meeting in September, 1890, that out of 100 Founders' shares in the Phœnix Trust Mr. F. L. Rawson held 25 or 50? I do not know whether it was defined at all; but we knew that we took a large interest in that Company for the purpose of bringing it out in order to assist Woodhouse and Rawson United.

Was it explained what the amount of capital was that was actually paid up?—No.

Was that material or not?—I cannot say.

You went into considerable negotiations, did you not, with the Phœnix Company? They bought a large portion of your shares and entered into very heavy contracts. Was it not material to know whether this Company really had any substance or not?—We were satisfied as to its being substantially able to do what it proposed.

How were you satisfied?—I cannot say what steps we took, but we were satisfied.

Supposing the shares had not floated—we know they were successfully floated by the Phœnix Trust, but supposing they were not—you would have had to fall back upon the Phœnix Trust. Now, I ask you, what had you to rely upon that the Phœnix Trust could pay the £75,000 for those shares?—My recollection may fail me, but as far as it serves me the value of those Elmore shares was assured when we made the arrangement with the Phœnix.

By Mr. H. G. Rawson: It was within his (witness's) knowledge that the Managing Director gave up half of his holding to the United Company. He had no doubt that when the matter was discussed the other members of the Board knew what the nature of the interest was which Mr. Rawson had in the Phœnix.

By Mr. F. L. Rawson: Before the formation of the Phœnix Trust offers were made by other trust companies to make practically the same arrangement as that entered into with the Phœnix. Witness could not say whether the Directors considered the nature of the constitution of the Phœnix Company and its capital, nor did he know that one of the trust companies alluded to offered Mr. Rawson the same proportion of Founders' shares as he afterwards received from the Phœnix.

By the Registrar: The Managing Director offered voluntarily to give up the shares. He said he had entered into the thing in the interests of the Company, and wished to share any profit which accrued.

The REGISTRAR: If he acted in your interest, why did he not give up all the shares?—He had individually acquired those shares, and therefore he was not bound to give them to us.

Then why did he make this present at all?—I am afraid your Honour must ask him.

The OFFICIAL RECEIVER: Can you say when the United Company took those Founders' shares?—I cannot say exactly, but about the time when the Managing Director informed us of the formation of the Phœnix Company and the objects of it.

The OFFICIAL RECEIVER: Long before the Elmore shares were purchased.

The REGISTRAR: That is so.

Mr. F. L. RAWSON returned to the witness box, and his examination was resumed by the OFFICIAL RECEIVER, who said: I want to draw your attention to a letter you wrote to Mr. Stutchbury in September, 1892, saying you would be glad to know whether he, whilst he was secretary or afterwards had known you take advantage of your position to do anything which was not in the interests of the shareholders, or that might not be considered right and proper for you to do. Mr. Stutchbury, in reply, questioned whether the Board fully understood from the commencement the nature of your connection with the Phœnix Trust Company, and that as a Director of the Phœnix Trust Company you were interested in the profits of that Company, and received from it a similar amount in dividend to the United Company itself, the profit of the Phœnix Company being principally derived from its connection with the United. Did you reply to that letter?—I do not think I did. I read it partly through to the Board, and they said: "Oh! we know all about that; we don't want to hear anything more."

Can you point to any minute?—It would not be entered in the minutes.

Did you tell Mr. Stutchbury that this letter was read, or partly read?—That I cannot say.

The OFFICIAL RECEIVER asked that Mr. Stutchbury might go into the box again.

Mr. STUTCHBURY was recalled, and said that he was present at the Board meetings at the time referred to. He did not think the letter was read, but he believed the Managing Director had it in his hand and referred to it. He would not like to swear that the matter of the Phœnix Trust was referred to; at many of the meetings he might be present for only 10 minutes, or a quarter of an hour. The reference in the letter to the telephone connection with Baron Grant's offices was mentioned. He did not think the Managing Director read the letter word for word, but summarised it.

Mr. F. L. RAWSON resumed: Mr. Philip Rawson and himself were constituted a committee with regard to the Okonite Company. He received authority, after a full discussion at the Board, to apply on behalf of the United for shares in the Okonite Company. He did not know whether it was mentioned in the minutes or not. The committee was appointed to sign all the cheques, the application forms, and everything else in connection with the Okonite matter. Mr. Philip Rawson might be unaware now that such a committee was formed, but it would be found that he signed the cheques. There ought to have been a minute on the subject, and it was a mistake if there was not. When the Okonite Company came out they applied for £15,000 worth of shares and debentures. They were obtained and sold, and it was afterwards considered that there ought to be a further purchase. In August it was settled what amount they would take up, and then the applications were made in the names of nominees in order that it should not be known outside that they were selling these shares and debentures. All the Directors were aware of this, except, perhaps, Mr. Pope, who, as a Director of the Okonite Company, would not vote or have anything to say about Okonite matters at the United Board except to give them information about the Company.

At this time you commenced buying yourself?—I lent money to the Company to do it.

At the time you were a considerable debtor to the Company, were you not? They had advanced you £28,000.—My recollection is that I had about £10,000 then.

Can you say how it was this money was repaid to you that you had advanced, as you call it, when you were already a debtor?—It was repaid according to the arrangement made.

The REGISTRAR said it was possible that a man might not be able to pay his debt, but to oblige his creditor might, by a special effort, raise a sum of money temporarily.

The OFFICIAL RECEIVER: It is rather unusual that a Director should be a considerable debtor to a Company, and I want to bring out this point, when the Directors were repaying these moneys to Mr. Rawson was it brought before them that at that time he was a debtor to them?—WITNESS: It is only fair to say that when I paid that £6,000 for the Okonite shares I said I might leave some of it with the Company, and there is a minute to the effect that I paid £600 as a part of my indebtedness, but there is no record in the books of that having been paid. Afterwards it was all paid back. I remember I said I could not afford to pay it.

Examination resumed: The circular as to the value of the Elmore shares was drafted by witness and considerably altered by Lord Aberdare. It was issued with the authority of the Board, and they had a good many letters and calls from shareholders thanking them for calling their attention to them. That might more properly have been the business of the Phœnix Trust Company. With regard to the circular announcing the retirement of Sir Albert Cappel, Sir John Coode, and Colonel Howard Vincent, there was a minute that the cause of their secession should be stated in the circular, and the fact that subscribers might claim to be repaid in full. Witness drafted that circular, and it was revised by the Directors. Witness offered to show the circular to the retiring Directors, but they refused to see it or to have anything to do with it. He was responsible for the clause as to subscribers having the right to withdraw being left out, but the circular was considerably modified after it was drafted. A copy was sent to all the Directors before it was sent out, and witness took it to the solicitors, Messrs. Budd and Johnson. Mr. Budd, who had been advising them, was away in Paris, and as there was great pressure of time witness consulted Mr. Johnson about it. He certainly acquainted Mr. Johnson with the fact of the minute requiring the statement that subscribers might withdraw. His reason for leaving it out was that he assumed all the subscribers, who were a particularly high class of applicants, would be perfectly aware of their right to withdraw. He felt certain at the time that he had done everything in regard to the matter that he ought to have done; but he felt now that he ought to have waited until a copy of the circular had been sent to Mr. Budd and approved by him. With regard to the notification to the bankers, the minute which said that was ordered to be sent was added at the succeeding meeting, when Col. Howard Vincent complained that the minutes had not been properly kept; but witness was certain that the original minutes were correct, and that no such resolution was passed.

You contested very strongly the decision not to go to allotment?—I wrote a letter to Sir Albert Cappel, thanking him for trying to induce Sir John Coode to consent to go to allotment.

Do you suggest that Sir Albert Cappel wanted to go to allotment?—Yes, and he tried to induce Sir John Coode, but Col. Howard Vincent said he did not see, in the face of the position taken by Sir John Coode, how we could do otherwise than agree with him. The difficulty with Sir Albert Cappel came when the writs were served.

The Official Receiver referred to Mr. Pixley's proposed certificate on the balance-sheet of 1891, in which he said that the figures did not disclose certain facts, that the gross profit consisted almost entirely of profits made on financial operations, and concluded by expressing the opinion that no dividends should be paid in money until the investments had been converted into cash. Was there anything incorrect in that statement?—WITNESS: As to the gross profit being made on financial operations, the Epstein profit was certainly not a profit made on financial operations, but on industrial; it was the working out of the Epstein patents. It was not a financial operation in any sense except that the patents were sold to a company, and the shares were put in at par. It was the result of hard work for something like two years by my brother and myself and Mr. Epstein. The last paragraph is a matter of opinion.

But Mr. Pixley never departed from that opinion, did he, as regards the inadvisability of paying a dividend?—Yes. He admitted it might be right to pay a 5 per cent. dividend; it was the payment of a 15 per cent. dividend that he objected to

Then you dispute his evidence?—There is no question about that. He admitted that to me.

He said he never advised the Directors to pay a dividend?—That is quite correct; but he admitted that there was no objection to a 5 per cent. dividend.

Digitized by Google

He says he advised them not to pay a dividend?—He never advised them not to pay a dividend of 5 per cent. That report was before he had gone into the matter and knew the values. Mr. Pixley said to me, "My advice to you is, as it always is, never to pay a dividend if you can possibly avoid it." He has exaggerated notions as to that. He said we should be merely putting responsibility upon ourselves, and it would be better to have the money in our pockets. That was not the view the Directors took.

There is a letter of October 15, 1891, from Mr. North to you, in which he says, "I have perused the proof balance-sheet which you handed me, and I have no hesitation in saying that it is, as now constructed, fradulent. I am sure no Director who values his character would pass it. When you consulted me about the balance-sheet for 1889-90 there were several things to which I took exception, but the present balance-sheet goes much further, and I trust a dividend will not be declared on such figures." Did you receive that letter?—Yes. That was at the time when I found out the practices of Mr. North, and he thought he would blackmail me and keep my mouth shut by writing that letter. He withdrew that letter, and said he had written it in ignorance of facts I gave him with regard to the care the Directors had taken in relation to these matters. Witness considered that a subsequent letter, which was read, and which went into details of the accounts, was a trimming letter. The impression on his mind was that Mr. North withdrew entirely when witness referred him to the Board. When he said witness was not to be blackmailed, he said, "Oh, well, I understand the Board have gone into these things. I never knew that." Then he withdrew his letter. Witness did not know that he showed either of the letters to the Board. At that time he had only discovered that petty cash had been taken; he was trying to find if there was anything further against North, and did not wish to go to the Board about the matter until he was sure of his ground, as he had already been called to account for complaining of Mr. North without being able to prove his case.

Witness was next taken through the investments, and questioned as to the values put upon them. He remembered a letter to him from the Secretary or Manager of the Okonite Company in October, 1891, saying that Company would pay no dividend that year, and requesting him not to make any reference to that Company at the meeting of the United Company's shareholders. He probably brought that letter before the Board, but in any case they were well aware that no dividend would be paid, owing to special circumstances. The Okonite shares were taken in the accounts at the Stock Exchange quotation of their value. Messrs. Budd and Johnson wrote, and quoted counsel's opinion, that an independent valuation of the Epstein shares should be taken, and the matter was discussed by the Board, who came to the conclusion that it was not worth while incurring the additional expense. There would have been a profit apart from the Epstein shares, for there was actually £4,000 paid on account of those patents, and there was his time and that of Mr. Stepney Rawson and the experts to be added.

At this point the examination was adjourned until to-day (Friday).

Cassel Gold Extracting Company v. Cyanide Gold Recovery Company and Others.

In the High Court of Justice on Monday last, Mr. Justice Romer commenced the trial of an action in which the plaintiffs claim that they are the registered owners of certain letters patent, numbered 14,174, of 1887, granted to John Stewart MacArthur, W. Forrest, and William Forrest for improvements in obtaining gold and silver ores and other compounds, and they allege that the defendants have infringed their letters patent. The defence was a denial of infringement and an allegation that the plaintiffs' letters patent were not valid, was different from that for which the patent was applied for, and was not new at the date of the patent, having been published in a number of publications, which the defendants relied upon as anticipations.

Sir R. WEBSTER, Q.C., M.P., for the plaintiffs, said that between 600,000 oz. and 700,000 oz. of gold had been successfully extracted by the plaintiffs' process, having a value of £2,500,000, and royalties had been paid to the extent of £117,000 in connection with the process. There had been a variety of methods of extracting gold, chemical, mechanical and electrical; but prior to this patent there was no method of extracting the residuum of gold from the tailings or washings of gold ore. The defendents invited persons to have their ores tested by the Pielsticker process, Pielsticker being the person who was alleged to have invented the infringing process. The defendants had permitted his clients to inspect what was being done at the laboratory of Mr. Harland, F.I.C., at Plough-court, Lombard-street, E.C. The suggestion was that they were not working to obtain gold by the dissolving action of the cyanide of potassium, but by electrical action, which had the effect of extracting the gold from the ore electrically, and not by the process Messrs. Forrest and MacArthur had described. The plaintiffs' case would be that electricity did not add anything to the dissolving power of the cyanide of potassium; and that the gold which was extracted was in the defendents' process got out by the dissolving action of the dilute solution in exactly the same way as in the plaintiffs' patent.

Professor James Dewar describel in technical language the operation of the plaintiffs' and defendants' patents as he understood them, and the use that had been made of cyanide of potassium as a means of extracting gold. He had seen the Pielsticker process, and it was his opinion that the separation of the gold from its ore was there brought about by the solution of cyanide of potassium. Heat was used in many of the previous methods. The ore in Rae's specification, dated 1867, was placed in cyanide of potassium solution and treated electrically. There was nothing in common between Rae's method and that of the defendants. Pressed as to this, witness admitted that in each case the ore was placed in a solution of potassium, and in each case the electric current passed through the ore and through the solution. Rae's and the defendants' methods were in principle the same thing.

Sir EDWARD CLARKE, Q.C., M.P., for the defendants, suggested a method of arranging the current so as to make Rae's patent work, but WITNESS declined to go into the causes which made Rae's patent fail, and added that it was not common knowledge to him that cyanide of potassium was effective for dissolving gold from its ore. Simpson's claim was for the process of separating metals from their ores, to wit, subjecting the ore to the action of a solution of cyanide of potassium, carbonate of ammonia, and chloride of sodium, and subsequently precipitating the dissolved metals. When this specification was produced he would have attributed importance to the presence of carbonate of soda and the chloride of sodium, but would not do so in his present state of knowledge.

Prof. DEWAR re-examined: The heat used in other methods was to produce the solution which was to be used. In Rae's patent there were two electrodes, and the electrodes in the first tank had nothing to do with the solution of the gold by the cyanide of potassium. There was no indication in Rae that you could get at the solution without electricity. The claims in Rae would not guide anybody to the patents owned by the plaintiffs. As far as he knew, Rae's patent was never used; certainly never used in England. Neither was the Sanders process, nor Simpson's.

Sir RICHARD WEBSTER said that no user was set up of any one of these anticipations, and that would be of importance.

Prof. ROBERTS-AUSTEN, F.R.S., Chemist of the Royal Mint, said he was well acquainted with the various processes for the production of gold from its ores. In 1887 he had never heard of the production of gold from its ores by means of cyanide of potassium. Before 1887 the great bulk of gold was extracted by the amalgamation process, by which almost any ore might be treated.

Mr. Justice ROMER: In Rae's process, as he describes it, has the electric current any influence in the solution?—Yes.

How does the electricity act differently in Rae's from the defendants' in promoting the solution?—In the case of Rae's the particles of gold are brought in contact with the anode, while in the defendants' they are suspended. The electricity in the defendants' process has no effect in promoting solution. He knew that there was such a work as "Chemistry Applied to Arts." In that book it was stated that Faraday found that ordinary gold leaf might be reduced in thickness without destroying it by means of a solution of cyanide of potassium, and that "cyanide of potassium is employed in the reduction of rarer metals from their ores," and from Faraday onwards all the books have referred to the solubility of gold in cyanide of potassium. The solution acted on the surface of the gold, and would necessarily act in the case of gold finely divided. The system of obtaining the ore from the solution was known at the date of plaintiff's patent, as was the fact that cyanide of potassium was a solvent of gold was known. The real question was the question of cost. At the date of the plaintiffs' patent there were undoubtedly difficulties in getting the gold out of solution, and, in answer to the learned Judge, the WITNESS admitted that Rae's patent got a solution for gold, and that Rae would have completed the problem if he had found a proper method of extracting that gold from the solution. Rae, however, thought that electricity would answer. The attenuated gold spoken of by Faraday was less than $\frac{1}{3000}$th of an inch. He had never heard of Rae's process being practically worked; but it would effect the solution of gold. Rae's method did not disclose any more than was known in electro-plating.

Lord KELVIN said that he had examined the Pielsticker process. In the plan shown to him the anodes and cathodes were at a certain point, and these had an electromotive force of less than two volts. The electricity thus produced would retard the action of solution. He had not experimented on this particular bath, but would expect to find the deposit on the cathode. Shown a trough on which he had experimented, he explained that he made the experiment to ascertain the effect of electricity in precipitating. A retarding effect was the result of the experiment. He also explained another experiment with an electric wire. Taken to the plaintiffs' plan, he explained that with the cyanide of potassium used with the anode and cathode, the anode having the gold, the gold would, by the solution, be deposited on the cathode. By Rae's process the electricity retarded the action. As to the effect of the solution according to strength, he corroborated the evidence of Profs. Dewar and Roberts-Austen as to the greater effect of the weaker solution. In Faraday's disclosures with regard to gold leaf, the relation of area to mass was of great importance. Faraday's specification would not lead anybody to the practical process of dissolving gold out of ore by that solution. The gold he used in the electric bath was smelted, but not annealed. The liquid could pass from one tank to the other. He did not test whether in its passage it had deteriorated. If it had, he felt sure that the deterioration would have remained on one side. Polarisation would protect the metal from the current going through it. Agitation of the liquid in the experiment he made would not have altered that result. The gold was not in the same state as it would be in the ore. In the experiment the gold was not so small as it would be in the crushed ore. The effect of the electricity would not be to dissolve the gold. Looking at Rae's patent, there was a cathode on which there should be a deposit. Rae might think he got the deposit through the current. In Pielsticker there was an electrical deposition, and the leaf of gold was suspended between the two terminals in the jar. A considerable portion of the current would pass through the gold. If the gold was in the ore, a much smaller portion of electricity would pass through. Assuming the gold leaf to be dissolved by the current, that would be in the solution; if time enough were given it would ultimately be on the cathode.

Mr. E. J. MILLS, F.R.S., Professor of Technical Chemistry in the Glasgow and West of Scotland Technical College, said that the specifications alleged to be anticipations did not disclose the use of cyanide of

potassium for the extraction of gold from its ore. He admitted that Rae's process was efficient for dissolving the gold in the ore.

Mr. Justice ROMER said that the sole question was whether the electricity going through the defendants' apparatus did have the effect of assisting solution, and asked witness why he did not try that.

WITNESS said that their experiments were conducted in a simple and trustworthy form, and there was nothing in the apparatus used which would vitiate the results.

Mr. R. TATLOCK, F.R.S., F.I.C., Public Analyst for Glasgow, said he was the author of an article on "Cyanide of Potassium," relied on in the particulars of objection, which said that "nearly all the cyanide of potassium made is used in electro-gilding, &c. It is also applied in the reduction of some of the rarer metals from their ores." That referred to the dry process, and not in any way to the wet process. The witness then corroborated previous witnesses as to the results of the experiments.

Dr. GEORGE GORE, F.R.S., said he never knew gold dissolved directly in cyanide of potassium for the purpose of forming a solution. Electricity was used in connection with electro-plating. Rae's and the defendants' processes were alike successful in dissolving the gold in the ore.

Sir HENRY ROSCOE said that the plaintiffs' process had rendered the economical extraction of gold from tailings possible. In the alleged anticipating specifications there was no case in which the cyanide of potassium alone was used for the purposes of extraction. Cyanide of potassium had long been used in conjunction with electricity in dissolving gold for electrolytic purposes. In his opinion, Rae's specification did not point to the fact that Rae knew that gold was soluble in cyanide of potassium without the aid of electricity.

In answer to his Lordship, WITNESS said that Rae might have thought that electricity was a facilitating agent. In his opinion, in the patent of Rae the use of electricity was an essential part of the process.

Mr. LOUIS JANIN said he knew at the date of Rae's patent that the solution of cyanide of potassium was effective for the purpose of getting gold in solution; but it was a special knowledge. The solvency of gold was generally known years before, but not of gold in ore. In 1840 Elkington used cyanide of potassium.

Professor CROOKES said the discovery of MacArthur and Forrest was that what was known to scientific men (namely, that a solution of cyanide of potassium would melt gold) was enlarged to apply to gold-bearing ores practically. The merit of the plaintiffs' invention was the applicatian of a scientific fact to practical use, showing that what was known in the laboratory, and had only been done on a small scale, could be applied on a large scale, and practically, to gold-bearing ores.

Mr. JOHN STEWART MACARTHUR, F.I.C., one of the patentees said that in 1886 he began the chain of experiments which led up to this patent. Before he experimented he had no knowledge that the cyanide of potassium could be practically used to extract gold from ore. Persons would not, he believed, have been led to that by the alleged anticipations. He understood Rae's process to be a simultaneous dissolving and depositing process. It was within his knowledge that Rae's patent was unworkable, and, in his opinion, nobody would have been led to the dissolving of gold by cyanide of potassium by Rae without the use of electricity. He had experimented to see whether the electric current had any effect in dissolving the gold in the ore, and found no beneficial effect. His results showed that the dissolution of the gold out of the ore was not assisted by the electricity. The conclusion that the electricity had no effect was arrived at from the fact that there was as much gold left when electricity was not used as when it was.

In answer to Sir Richard Webster, WITNESS said that 36,000oz. of gold per month was being obtained by his process, which otherwise would have been lost.

By His LORDSHIP: The electricity was not renewed in the experiments.

Sir EDWARD CLARKE: But in the defendants' process the solution is regenerated?

WITNESS said that was the statement of the defendants, but he had reason to doubt it. When the electricity was removed from the defendants' process it became the MacArthur process. He had no special knowledge that his patent would not deal successfully with American ores.

WITNESS was being taken to his subsequent American patents when Sir Richard Webster objected.

Mr. JUSTICE ROMER thought it might help the defendants by showing the reason why Rae's process was not worked.

Sir EDWARD CLARKE said it would help them by showing that the plaintiffs' patent was not applicable to all forms of ore, though it happened to be applicable to the particular ore of Africa. Rae's method would dissolve the gold from the ore, but he thought it would not be possible to precipitate the gold from solution in Rae's process. One of the weak points in Rae's process was the precipitation. Experiments could be made again if necessary. The process of using zinc for the recovery of gold was well known at the date of the patent, and zinc shavings were an improvement of that process. Zinc was not used for the purposes of forming the solution.

Mr. GEORGE MACCULLOCH, Chairman of the African Gold Recovery Company, said there was still some gold in the tailings which could not be dealt with. He should say that about one-half of the present production would not exist but for the introduction of the cyanide process.

Sir EDWARD CLARKE, Q.C., M.P., for the defence, submitted that the plaintiffs had made out no case. The claim was for any solution containing cyanogen or cyanides, or any other substance containing or holding cyanogen. That was the largest claim that could possibly be made. It was admitted that for years it had been well known that an aqueous solution containing cyanogen had the property of dissolving gold. Under these circumstances he submitted that there was no subject matter of invention at all. What novelty and what ingenuity could it be suggested there was in the plaintiffs' patents?

Mr. JUSTICE ROMER intimated that he was with the defendants on several points; but would not determine the case without hearing the evidence.

[The evidence for the defence will be given in our next issue.]

Davies v. R. Bolton and Co. (Limited).

This was the action in which Mr. Justice Vaughan Williams had referred to the insufficiency of the existing law with reference to debentures, and was important as showing how far persons dealing with companies are affected by irregularities in the internal affairs of those Companies. The action was originally brought by Mr. G. L. Davies against the Company (in liquidation) to enforce a First Mortgage Debenture on all the Company's assets, issued to Reginald Bolton, to secure a sum of £649. 1s. 3d., with interest at 5 per cent. This debenture was directly afterwards transferred to Davies, and after the commencement of the action it was transferred to Mr. Cecil Fane, who obtained leave to continue the proceedings. The action was defended, in the name of the Company, by the Official Receiver and Liquidator.

Mr. Justice WILLIAMS said the case raised a question of some general and public importance. The practice of insolvent traders turning themselves into limited companies and then issuing debentures in favour of some, or all, the creditors of the particular trader—debentures which secured really the price that was payable by the Company to the vendor—had of late years become extremely frequent. It was quite clear that in many cases the whole operation was a mere fraud. It involved conduct which, if it was that of an individual trader, no one would hesitate to describe as a fraud on his creditors. He was glad to say the present case was not a flagrant instance of the user of the practice referred to. Mr. Bolton was not present, and his Lordship did not wish to say anything against him. He had apparently absconded. He entered into partnership with Davies, and his Lordship was not surprised that it turned out unsatisfactorily, and that Davies was glad to get out of it at a sacrifice. After such sacrifice had been made there was still a considerable sum due from Bolton to Davies. After this Bolton turned himself into a company, not with a view to benefiting Davies, but rather in a spirit of hostility to him. Thereupon Davies put the matter into the hands of his then solicitors, who pressed Bolton for payment. Bolton was unable to pay the amount due, but said the Company had to pay him for the purchase of the business, and anticipated that the sum would come in from the shareholders; but that if Davies pushed matters very far Bolton might become bankrupt, and there would be a loss to the creditors. The debenture in question in this action was given, and it was the duty of the Court to consider the various objections which had been raised to it. He was of opinion that the seal was affixed to the debenture so as to bind the Company. Bolton was a Director, and certain clerks and friends were the other Directors, but Bolton was the beginning, the middle, and the end of the Company. When the Court was satisfied that the seal of the Company had been affixed to the debenture in the course of business by those who had the management and control of the Company, non-compliance seemed to come within the terms of and to be cured by article 115 of the Articles of Association of the Company. The debenture must be held valid, and the plaintiff was entitled to have it enforced.

The question of costs was reserved. The debenture included all the assets, and his Lordship said he should not make any order which would involve payment of costs by the liquidator personally unless he was satisfied that that was the ordinary practice followed by the Judges of the Chancery Division.

Reddaway and Company Limited) v. Barnham and Company (Limited).

At Manchester, last week, Mr. Justice Collins and a special jury, this case was heard. It was an action for an injunction to restrain the defendants from continuing to infringe the plaintiffs' registered trade marks, and from continuing to use the word "Camel" in such a manner as to pass off their beltings and driving bands as the plaintiffs' goods, and for an account or damages. It was claimed by the plaintiffs that from 1879 to 1892 they had manufactured and sold at home and abroad large quantities of belting having the word "Camel" or the figure of a camel upon it, so that the word was universally understood to indicate that goods to which it was attached were of the plaintiff's manufacture. The defendants denied that there was any such universal understanding, and said that they had made and sold a belting known as "camel-hair belting," such belting being of a particular kind and the words being descriptive of the material used in its manufacture. They had used this description of their belting for some time prior to the incorporation of the plaintiff Company, and to the knowledge of, and without any objection on the part of, one of the plaintiffs.

After hearing evidence the jury returned a verdict for the plaintiffs, and an injunction was granted. An application to suspend the injunction was refused, and the plaintiffs were allowed costs on the higher scale.

In re Medical Battery Company (Limited).

In this action a scheme of arrangement has been sanctioned under the Joint Stock Companies Arrangement Act, 1870, but "only on the condition that the memorandum of association of the new Company (to be formed to purchase and carry on the business) should be so framed as to provide that electrical treatment and the sale of electrical belts should be under the control of a duly-qualified medical assistant, "who would be

Digitized by Google

present when each belt was sold (!) The memorandum as altered must be produced to the Registrar.

Under the scheme it is proposed to raise £3,000 by First Debentures, the present debentures to take second place. There are to be six new Directors, the old Directors to have no connection with the Company.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1894 Edition of "The Electrician" Electrical Trades' Directory and Handbook contains 1,000 closely-printed pages, and several new and useful features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d. *The 1895 edition is in preparation.*

"Electric Lamps and Electric Lighting," being four Lectures delivered before the Royal Institution in April-May, 1894, by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is in preparation, and will shortly be published.

"Electromagnetic Theory," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

"The Incandescent Lamp and its Manufacture."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application to the Publisher.

"Drum Armatures and Commutators."—This book, written by Mr. F. Marten Weymouth, is also ready; price 7s. 6d (abroad 8s.). Prospectus on application.

"Inventions, Researches and Writings of Nikola Tesla," by T. Commerford Martin, may be obtained from the Publisher of *The Electrician*, and a copy will be forwarded post free on receipt of 16s. 6d.

"How to Wire Buildings."—Copies of this work, by Augustus Noll, will also be sent by the Publisher post free on receipt of 6s.

"Electrical Engineering Formulæ," a pocket-book by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher

Tenders Invited.—The Great Yarmouth Corporation require tenders for installing the electric light at the School of Art. Tenders have to be in before noon of the 30th inst. to Mr. T. M. Baker, town clerk.

Tenders Accepted.—The Electric Lighting Committee of the Burgh of Ayr have, we are informed, decided to place the contracts for the plant required for their new electricity works with the undermentioned firms:—

Siemens Bros. and Co. (Limited), engine-house plant	£5,940
Callenders Bitumen Co. (Limited), cables and culverts ...	1,842
Penman and Co., boiler-house plant	1,541
S. Z. de Ferranti (Limited), meters	590
John Fowler and Co. (Limited), Leeds, arc lamps & posts.	476
John Fowler and Co. (Limited), Leeds, switchboard	437
Swinburne and Co. (Limited), transformers and boxes ...	420
Carrick and Ritchie, overhead crane	192

We are also informed that the absence of the names of the Brush Electrical Engineering Company, Messrs. Crompton and Co., and of the Electric Construction Company is due to the refusal of these firms to tender to the specification. The full list of tenders received will be found in our issue of the 13th inst.

——— The Melbourne City Council have accepted the tender of Messrs. G. and C. Hoskins for the supply of 900 30ft. poles for electric lighting purposes, at £1. 3s. 4d. each. The tender of the same firm has also been accepted for erecting and painting 1,344 poles for the sum of £425. 12s.

Tenders Received.—The Belfast Corporation have handed over the tenders received for a travelling crane for the new electric lighting station to Mr. McCowen, the resident electrical engineer, to report upon.

Liquidations.—The petition for the compulsory winding-up of the Collier Audible Telephone Syndicate (Limited) was disposed of on Thursday by Justice Vaughan Williams. The Company was formed for the purpose of working a certain patent, and in March, 1892, entered into agreements by which in effect it transferred its undertaking to another company called the Collier-Marr Telephone and Electrical Manufacturing Company, subsequently going into voluntary liquidation. The present petitioners, Messrs. W. Shepherd and Sons, were creditors, and, on the ground that the voluntary liquidation had been going on for over two years without a satisfactory result, asked for a compulsory order. His Lordship made the order, as requested.

Receivership.—The Halifax and Huddersfield Union Banking Company applied last week to Mr. Justice Chitty for the appointment of a receiver and manager for the business of Andrews and Preece (Limited), electrical engineers, of Bradford, of which Company the bank were debenture-holders. Mr. James Duff, accountant, Halifax, was, by consent, appointed receiver and manager.

Dissolution of Partnership.—The partnership between Messrs. T. Somers, A. Firth, and J. Bowns, trading as the Baker Blower Engineering Company at Stanley-street, Sheffield, has been dissolved, the business being continued under the control of Mr. T. Somers.

Appointment.—Mr. A. B. Mountain has been appointed by the Huddersfield Corporation borough electrical engineer and manager, at a salary of £250. Mr. Mountain was selected in December, 1891, to superintend the laying of the mains and the erection of the electric lighting machinery. For these duties he received £200 a year, and it was pointed out, at the meeting at which his appointment was now confirmed, that the electric lighting department was making satisfactory progress.

Vacant Appointment.—The Town Council of the City of Cape Town invite applications from qualified engineers for the office of electrical engineer to manage the Electric Lighting Department of the City, at a salary of £400 per annum. Further particulars are given in our advertisement columns.

New Address.—Members of the electrical trades, and buyers generally, are informed that the Telegraph Manufacturing Company, of Helsby, near Warrington, have, in addition to their establishments in London, Liverpool, and Glasgow, now opened a branch to serve the Lancashire and Yorkshire districts at 2, Parsonage, Manchester, where stocks of the Company's manufactures will be kept. Telegrams should be addressed "Vigorous Manchester."

New Firm.—Mr. J. D. Miller, M.I.E.E., who was formerly with the National Telephone Company, has started business as a consulting electrical engineer in Dundee.

Personal.—Messrs. Gabriel and Angenault have secured the services of Mr. George Davis for the management of their London Depot at Connaught-mansions, Victoria-street, S.W., where a stock of incandescent lamps of their manufacture will be kept. Mr. Davis has been with the St. James's and Pall Mall Company as Inspector since the foundation of that Company in 1889.

Admiralty Contracts.—The United Asbestos Company (Ltd.), of Dock House, Billiter-street, E.C., have been successful, for the tenth time, in securing the contract with the Lords of the Admiralty for the supply of "Victor" metallic joints and other asbestos goods for use in Her Majesty's Navy.

Messrs. Drake and Gorham.—This firm have in hand in London the entire reconstruction, rewiring, and additions to Mr. Bruno Schroder's mansion at Kensington-court, S.W., for about 70 lights, and Mr. Harris's house in Montagu-square, for 32 lights.

Boudreaux Dynamo Brush Company.—This Company are issuing printed particulars of their latest form of foliated rolled metal dynamo brushes, and a list of many of the principal users in England, France, Belgium, and Austria. The names of many of the principal firms in those countries are included in the list. The Company are agents in this country for Labour's alternating-current generators and transformers, and Desruelles' and Chauvin's patent ammeters and voltmeters, of which particulars and prices are now ready.

The "Hercules" Belt Fastener.—Hercules was strong, and he cleansed the Augean stables. Hence his connection with leather, though it is doubtful if horse hide is any good for belts. However, the "Hercules" belt fastener is claimed to be strong and is intended as a leather connection. In itself it is undoubtedly stronger than the leather which it is designed to bind, being made of steel; but the danger with this kind of fastener is that there is a liability of the leather being torn. In the "Hercules" belt fastener this danger is obviated by the use of a kind of cover plate to distribute the stress over the leather instead of allowing it to be concentrated at the joint holes. The fastener makes a strong and neat joint, having the combined advantages of strength, flexibility, and smoothness. It is made by Messrs. Honeywood, Austin and Co.

McDougall's Steam Saving Appliances.—It is scarcely necessary to point out the vital importance of the economical use of steam in electric supply stations and other steam-driven works. The Chadderton Ironworks Company (Limited) have recently sent us a copy of their illustrated catalogue, descriptive of the McDougall steam-saving appliances manufactured by them. From a list we see that these appliances, which comprise steam separators, driers, traps, anti-priming pipes, and oil separators, as well as the McDougall system of mechanical stoking for steam boilers, have an extensive and increasing use in electric supply works.

Digitized by Google

WELDED PIPES.—Mr. John Spencer sends us illustrated particulars of his patent welded iron and steel socket and spigot pipes and flanged pipes. The spigot-and-socket tubes, made from 2in. to 6in. diameter can, it is claimed, be fixed by the workmen accustomed to the old lead and yarn joint, and as these tubes can be made about one-half the weight of cast iron pipes, and in lengths more than double that now in common use, the cost of freight and of all jointing is considerably reduced, as is also the loss by breakage in transit. The welded flange pipes are made to take the place of brazed-on flanges and of cast-iron pipes also. As Mr. Spencer points out, there is nothing new in welding pipes into flanges; but the newly-patented method is devised to provide a flange pipe which is as strong at one part as another, or, in fact, may have an increase of strength at the welded point. The weight of these pipes is claimed to be much less than that of cast iron. Important tests have been made particulars of which are given in the printed sheets.

ABERYSTWITH.—The whole of the 17 arc lamps have been erected on the Marine and Victoria-terraces18; further arc lamps are to be put up within the borough and on the chain pier.

ADELAIDE (SOUTH AUSTRALIA).—A pamphlet has been prepared by the South Australian Gas Company entitled, "The Electric Light as Applicable to the Lighting of the Streets of Adelaide." The pamphlet is prepared with the special view of instructing the citizens of Adelaide on the advantages and disadvantages (but principally the latter) of electric lighting. The authors have used considerable ingenuity in preparing statistics of small failures with the view of proving to the citizens of Adelaide that the electric lighting scheme which the City authorities have under consideration will prove disappointing to the projectors and to the ratepayers.

ANNUAL DINNERS.—The employés of the Kensington and Knightsbridge Electric Lighting Company (Limited) held their fifth annual dinner on Saturday last at Crampton's Hotel, Ramsgate, Mr. H. W. Miller presiding.——The annual outing of the employés of the City of Bath Electric Light and Engineering Company (Limited) took place on Thursday last week, at Badminton, the seat of the Duke of Beaufort.

ARMY AND NAVY STORES.—The extensive depots of these stores, situate in Coburg-row and Francis-street, Westminster, are to be lighted by electricity from designs by Mr. Bernard R Drake. The contract has been placed with Messrs. Crompton and Co. (Limited), whose tender was the lowest received from the firms nominated by the Army and Navy Stores to submit tenders.

ARUNDEL CASTLE.—Amongst the many important improvements recently introduced by His Grace the Duke of Norfolk at Arundel, which include almost the entire rebuilding of the castle itself, may be mentioned an electric lighting installation of considerable magnitude, which will be when completed one of the most important in the country. The building intended for the generating station is situate near the entrance to the castle gardens, and is provided with an octagonal shaft 46ft. in height. This building has a total frontage of 92ft., with a depth of 48ft., and a height of 36ft. It comprises boiler house, engine room, accumulator room and fitting shops. The plant consists of three Galloway steel boilers with Atkinson's feed-water heaters attached Three 90-H.P. vertical compound engines have been put in, coupled direct to specially compounded six-pole dynamos capable of working up to 400 amperes. The accumulator room contains two battery sets of 62 cells each. The castle itself is situated about 500 yards from the generating station, and is lighted throughout by incandescent lamps of various candle-powers. Incandescent lamps are to be used for the courtyard and the drive from the lodge. The various plans sent in for lighting the castle were placed in Mr. W. H. Preece's hands for selection, Mr. G. Kapp acting as consulting electrical engineer to the Duke. Mr. A. F. Phillips, C.E., has superintended the building and general arrangement of the plant, the contractors for the buildings being Messrs. Read, Bright and Co. The Brush Company have supplied the whole of the machinery and electrical plant, and the work has been carried out under the superintendence of Mr. W. Geipel, the Brush Company's superintending engineer, Mr. A. Bard, C.E., acting as resident engineer. Mr. J. E. Sayers has been in charge of the electrical part of the work, and Mr. J. W. Donnet of the mechanical department at the station.

BALLAARAT (VICTORIA).—The Ballaarat Electricity Supply Syndicate has concluded an arrangement with the Victorian Government Railway authorities for lighting the various local stations and embankment at Ballaarat by electricity. The Government will, it is stated, save about £300 per annum by the introduction of the new light as a substitute for gas. The post and telegraph offices and other public buildings are shortly to be lighted by electricity, so will also the mechanics' institute. The leading shopkeepers of the city promise their support to the syndicate.

BELFAST.—It is expected that some of the engines for the electric light plant will be ready for testing in about a week's time. Numerous applications have been received for electric current from parties both inside and outside the electric lighting area.

BURTON-ON-TRENT.—In the abstract of borough accounts for the past year, issued by Mr. Fish, the accountant to the Corporation, it is stated that the amount raised for introducing the electric light into the borough was £25,992, of which sum £14,095 was expended up to March 25th last. The net profit from the gas department proved to be the lowest since the incorporation of the town in 1879.

CARDIFF.—The Lighting Committee of the Corporation have been requested to include the Free Library in their inspection, with the object of ascertaining the cost of lighting the building by electricity.

CHELSEA (LONDON, S.W.)—It is expected that the electric lighting work at the Town Hall will be completed in about a fortnight. Many complaints have been received from those who hire the Hall for evening meetings at the discomfort caused by the gas, and the change to electric lighting will doubtless be fully appreciated.

CHURCH LIGHTING.—St. Martin's Church, Scarborough, is being installed with the electric light. About 100 lights will be used.

COUNTRY HOUSE LIGHTING.—Yestor House, Haddington, N.B., the seat of the Marquis of Tweeddale, is now fitted throughout for the electric light. Motive power has been obtained from the Mains, situate half a mile distant from the mansion. About 300 incandescents are used, the generating plant being supplemented by a battery of accumulators. The work has been carried out by Messrs. A. A. C. Swinton and Co.——Jordanston House, Blairgowrie, which is in course of erection, is being fitted for the electric light.

EALING.—The buildings of the central electric lighting station at Ealing, erected to the design and under the superintendence of Messrs. Bramwell and Harris, are approaching completion, the directors being Messrs. Wilkinson Brothers. The lighting plant is being put in by Messrs. Siemens Brothers and Co., the boilers by Messrs. James Watt and Co., and the mains by the Callender Company. It is expected that the supply of current will commence in September, the official opening taking place on the 29th of that month. An electrical exhibition is to be held in the Victoria Hall, or other suitable place, where customers will have an opportunity of selecting fittings suitable for their particular necessities. Exhibition will be made of the various applications of electricity to lighting, domestic, and other purposes.

EAST HAM.—An application from the Local Board to the West Ham Gas Company asking for a reduction in the price charged for gas supplied to the public lamps has received the same negative reply as did that of the West Ham Corporation a short time back. At the last meeting of the Local Board the reply from the Gas Company was discussed, and it was the opinion of members that the time had come when the Board should take some steps to light the public streets by electricity. Mr. Keys, a member, pointed to the fact that the hospital was lighted by electricity, by means of power from the sewage works, and this had proved a great success. The surveyor to the Board, in the course of his remarks on the subject, said that he hoped that the time would shortly come when they would not only have the town lighted by electricity but would also have electric tramways.

EDINBURGH.—Mr. Treasurer M'Crae has presented the year's Corporation accounts, and in the course of his introductory statement said that they had not spent all the money last year that they had estimated for electric lighting purposes, and therefore the electric light did not show such a large increase on the year's expenditure as might reasonably have been anticipated. There was only an increase of £1,725.

ELECTRICAL EXHIBITON AT WORCESTER.-As previously announced, the Worcester Corporation have arranged to hold a popular exhibition of electrical appliances in October next, coincident with the opening of the supply station. The Corporation invite plant, apparatus, and fittings makers to apply for space, which, as well as electric current, will be supplied free of charge. This spirited and liberal policy should prove attractive to manufacturers and dealers, and result in a varied and extensive display. Its effect will doubtless be to increase the popularity of the electric light installation, considerable interest in which is being manifested locally, as is proved by the fact that orders have been already received for nearly 3,000 lamps. The Corporation intend using the current for lighting the streets, and driving a portion of the pumping machinery at the water-works.

ELECTRIC ORGAN.—Messrs. Hele and Co., of Wyndham-street, Plymouth, are erecting in the music saloon of Sir Gervas Glyn's house in Surrey a new organ, fitted with the Hope-Jones electric action. The organ has four keyboards, which can be played at a distance of 50ft. from the instrument.

EXETER.—It has been decided by the City Council to light the new wing of the museum building by electricity. The foundation stone is to be laid by the Mayor on August 1st.

Digitized by Google

FAREHAM.—The burning question as to whether the Local Board should purchase the local electric lighting company's undertaking for £6,500, or whether the value of the Company's undertaking should first be ascertained by an independent valuer, was thoroughly discussed at a meeting held at the Town Hall last week. The general opinion was that the Company's business should be taken over by the Local Board. It was ultimately decided that the Local Board be instructed not to sign the contract until the independent valuation had been made. This motion was strongly opposed by the members of the Board, who insisted that a very reasonable bargain had been struck with the Company, and one which would considerably benefit the town.

FISHMONGERS' HALL.—The electric light is to be fitted throughout the whole of the premises of the Fishmongers' Company at London Bridge, S.E., under the supervision of Messrs. Massey and Allpress.

GLASGOW.—A sub-committee, recently appointed to consider the question of the liability of the Police Commissioners in the matter of telegraph wires, has received an account for £349 from the engineering branch of the Post Office for the work of diverting underground wires from the Glasgow bridge to the temporary new bridge, and it was pointed out that, although the Corporation received no payment for way-leaves granted to the Government for running telegraph wires over the bridges under the custody of the Corporation, when these wires have from any cause to be removed or diverted the work is done by the Post Office officials at the expense of the Corporation. After some discussion the solicitor pointed out that there was no remedy, and the account was passed and the subject dropped.

HALIFAX.—Sixty-three applications for electric current have already been received by the Local Board from the principal tradesmen of the town. The Masonic Hall Committee have also decided to introduce the electric light into their buildings.

HAMPSTEAD.—It is proposed (provided the Metropolitan Asylums Board agree to take from the Vestry the electric current required at the North-Western Hospital) to lay the necessary mains and transformers through Buckland-crescent, Belsize-park, and Belsize-avenue, to the hospital, of sufficient capacity to supply the private consumers in those roads and the Vestry Hall, the total estimated cost of the work being £1,734. A proposal to still further extend the mains to property in course of erection in the South End Green district, was referred to the Electric Lighting Committee for their consideration.

HARROW.—It was announced at the last meeting of the Local Board that the Electric Lighting Provisional Order had passed both Houses of Parliament. A meeting of ratepayers had been held, at which certain statements had been made which had been put into writing and submitted to the Electric Lighting Committee for consideration and report. It was suggested to call in the services of Prof. A. B. W. Kennedy at a fee of 100 guineas. After some discussion the subject was referred back to the Committee.

HEYSHAM.—The Lancaster Rural Sanitary Authority have given their consent to the local electric lighting company applying to the Board of Trade for a licence to supply the Heysham district with electric current.

HULL.—The electrical engineer, Mr. A. H. Gibbings, has presented a report to the Electric Lighting Committee of the Corporation, in which he suggests that additional engines and dynamos of 600 H.P. should be purchased and erected, to meet the demand for the coming winter, at an estimated cost of about £4,500. It was resolved to print the report, so that the matter may be fully discussed at the next meeting of the Corporation. The electrical engineer reported that the Electric Light Department had now 176 consumers on their books.

ISLINGTON (LONDON, N.)—It has been decided by the Vestry to purchase additional land and property adjacent to the site adopted for the central electric lighting station at Eden-grove and Bernard-place, Holloway, in view of extension being necessary in the near future. It has further been decided to apply to the London County Council or some other body for a loan of £51,000 for 42 years at 3½ per cent. interest, repayable on the annuity system, the money to be devoted to the purposes of completing the electric lighting works.

KINGSTOWN (IRELAND).—During the regatta festivities this week several outdoor displays have been given, much interest being taken by the spectators in the lighting of the front of the civic headquarters with about 750 8 and 16-c.p. incandescents.

LEWISHAM (LONDON, S.E.)—The District Board of Works have received a memorial signed by 10 residents, complaining of a nuisance alleged to be caused by the works of the Crystal Palace and District Electric Supply Company. It was resolved to take the usual steps to lay the complaint before a magistrate, when the memorialists will be called upon to prove the nuisance.

LONDONDERRY.—The opponents of the Corporation's electric lighting scheme have succeeded in bringing about a crisis which has led to the resignation of Mr. Magee, Chairman of the Electric Lighting Committee. It would appear that a short time back the sum of £2,130 was required for the supply and erection of additional arc lamps for public lighting, and the Local Government Board was notified of this fact. A query arose as to whether the Corporation had duly passed a resolution asking for powers to borrow this sum, and as this formality had been dispensed with, and as Mr. Magee, as Chairman of the Electric Lighting Committee, was responsible for the application being made, his opponents succeeded in passing a resolution which Mr. Magee considered as one of want of confidence, and tendered his resignation. Mr. Magee pointed out that statements were constantly made in order to injure the electric lighting scheme, which, notwithstanding, was for the benefit of the public. It was ultimately decided to notify the Local Government Board that the letter sent to them on the subject was unauthorised, and, upon this motion being carried, Mr. Magee tendered his resignation. The gas element in the Corporation were scarcely able to control their gratification at the success of their manœuvres; but it is scarcely necessary to point out that, whether Mr. Magee is again induced to accept the post of Chairman of the Electric Lighting Committee or no, the Londonderry electric lighting scheme will go on and prosper, despite its opponents. There are few districts where the electric light and its sponsors have met with more strenuous, and not always straightforward, opposition than in Londonderry. But this has not prevented the scheme making sure, if slow, headway.

MAIDSTONE.—The Electric Lighting Committee have reported to the Local Board that, owing to no satisfactory arrangement having been come to with the Company with which the Board had been in negotiation for the transfer of its Provisional Order, a new advertisement is to be issued by which the Board ask for offers to be sent in by responsible firms for taking over the Order. In discussing the Committee's report, which was subsequently adopted, several members pointed to the opposition with which from the first the electric lighting scheme had been received; in fact, the gas interest had proved too strong for those who felt sufficient pride in the town to propose the adoption of the newer and better illuminant. It was pointed out that the advantage the Board possessed over any company likely to undertake the Order was that they were in a position to borrow at 3 per cent., whereas a company would be expected by its shareholders to pay 5 per cent. on its capital.

MELBOURNE (VICTORIA).—It has been decided to re-engage Mr. A. J. Arnot as electrical engineer to the City Council for three months, dating from June 9th.

MILL LIGHTING.—The extensive flour mills occupied by Mr. A. Robinson, at Norwood Bridge (Surrey), have been lighted throughout by electricity, 100 16-c.p. and a few larger lamps being used. The residence of the proprietor in the rear of the mill is also lighted by electricity, a separate building having been provided for the generating plant. The work has been successfully carried out by Mr. Wilson Hartnell.——The mills occupied by Mr. E. Barlow at Radcliffe are being fitted with the electric light, about 300 incandescents being used. The work is being carried out by Messrs. Bennett and Druce, who have also an installation for 250 lights at the Preston Industrial Co-operative Society's premises in hand.

MORECAMBE.—The local Electric Lighting Company have succeeded in abating the nuisance complained of at the electric lighting station, to the satisfaction of the local authorities.

NEWCASTLE-ON-TYNE.—Although the number of electric lamps erected by the Newcastle Corporation is limited, the result of the experiment has given the greatest satisfaction, and it is stated that the Corporation is taking steps to acquire, if possible, the plant and undertakings of the electric lighting companies established in the town; or, as an alternative, to come to an understanding respecting an adequate provision for the electric lighting of the city. It will be remembered that the sum of £200 was voted at the last meeting of the Council for the purpose of employing an expert to advise as to the cost of an electric lighting scheme for the city. No selection was made at the meeting on Tuesday, as the Corporation's city engineer is in London making further inquiries on the subject.

PORTSMOUTH.—The Corporation electric lighting installation is, we understand, giving the greatest satisfaction, and considerable extensions will shortly have to be effected. Applications are being constantly received from localities outside the present supply area, and, as sufficient orders come in, the Electric Lighting Committee have decided to take the necessary steps to extend the mains. The authorities of various places of worship are discussing the advisability of introducing the electric light, and the South Parade Pier Company have already decided to light the pier electrically.

RUSSIAN CUSTOMS TARIFFS.—A number of alterations have been made in the Russian customs regulations recently and the classification of certain articles have undergone considerable modification.

Digitized by Google

Parts of dynamo-electric machines under Section 167 now pay a duty of from 1 rouble 40 copecks to 4 roubles 32 copecks in gold per 36lb. weight according to the metal of which they are made. Belts pay a duty of 20 copecks in gold per Russian pound. Under Section 147, iron, steel, or copper wire, and electric cables of all kinds when coated or covered with other common metals, are to be cleared under the rules of this section. Other changes affecting the electrical and allied trades have been made, particulars of which can be obtained from the Board of Trade.

SEVENOAKS.—The Holloway Electricity Supply Company have notified the Local Board of their intention to apply for a Provisional Order to enable them to supply electric current in the Sevenoaks district. Opinion was divided as to the advisability of the giving or withholding of consent to the application.

SHOREDITCH (LONDON, E.)—At the last meeting of the Vestry it was proposed to appoint Mr. Manville, of Messrs. Kincaid, Wal'er and Manville, consulting electrical engineer in connection with the proposed supply and erection of electric lighting plant at the Pitfield-street station at a commission of 3 per cent. on the amount of the lowest tender received. The matter is to be decided at the next meeting of the Vestry.

STOKE-ON-TRENT.—The North Staffordshire Railway Company have now introduced the electric light for the whole of the extensive station buildings at Stoke, including the range of underground passages.

SYSTEMATIC DAMAGE.—Ernest Lawrence, a carriage cleaner, employed on the District Railway, was brought up at the West London Police-court on Tuesday last, charged with wilfully breaking open a reading lamp, the property of the Railway Automatic Electric Light Syndicate (Limited), with the intention to steal money therefrom. It appeared the Company had lost considerable sums from the lamps, and suspicion had fallen upon some of the railway servants. The prisoner was only charged with damaging one lamp, but a number of others in the same train were found injured. The prisoner had been watched, and the present charge was made. The prisoner was committed to gaol for two months, with hard labour.

THEATRE LIGHTING.—We recently stated under this heading that the gas-engines required in connection with the lighting of the Theatre Royal, Bradford, were supplied by Messrs. Crossley Brothers. Messrs. Tangyes (Limited) ask us to state that this is an error, the engines supplied being Tangye engines.

WINDSOR.—It has been decided to apply to the Board of Trade to revoke the Windsor Electric Lighting Order for 1890, and to apply for a Provisional Order for power to light the districts of Eton and Windsor in place of the Order it is proposed to revoke. The Electric Lighting Committee of the Town Council have been collecting informations from Local Authorities who are either using or contemplating adopting the electric light, and the whole subject will be discussed at an early meeting of the Council.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

July 16, 1894.

13,652. CHARLES ESSON. London. Improvements in electric switches.

13,700. J. EDWARD KINGSBURY. London. Improvements in telephone switchboard mechanism. (The Western Electric Company, U.S.A.)

13,706. A. H. ENTWISTLE, H. G. STEPHENS and A. DUBBER. London. An improved shade for electric lighting and like purposes.

13,714. LUDWIG JAROLJINEK. London. Improvements in or relating to the exploding of blasting charges in mines.*

July 17, 1894.

13,728. ALFRED DICKINSON. Darlaston. A combined pole and lamp post for supporting overhead wires or cables for electric tramways or railways, telegraph, telephone, and other wires or cables.

13,744. JOHN ELDRIDGE SPRATT. London. Electro-magnetic massage roller.

13,747. WILLIAM W. STEVENSON. London. An improved electrical coupling or terminal.

13,749. CHARLES A. ALLISON. London. Improvements in electric signalling apparatus. (The Standard Electric Signal Company, U.S.A.)*

13,750. CHARLES A. ALLISON. London. Improvements in electric signalling apparatus. (The Standard Electric Signal Company, U.S.A.)*

13,751. CHARLES A. ALLISON. London. Improvements in electric signalling apparatus. (The Standard Electric Signalling Company, U.S.A.)*

13,756. CHAS. NELSON WAITE. London. Improvements in, or connected with, electrolytic cells and diaphragms therefor.*

13,762. CHAS. DANIEL JENNEY. London. Improvements in and relating to electric railways.*

13,765. E. HIBBERD JOHNSON and R. LUNDELL. London. Improvements in and relating to electric railways.*

13,771. EDWARD LACHMANN. London. Improvements in and relating to electric railways.

13,791. W. LLOYD WYNN WILLIAMS and G. H. MORGAN. Liverpool. Improvements in or appertaining to incandescent electric lamps.

13,794. G. WASHINGTON EISENHUTH, R. HERMAN and EMILE H. HERMAN. Liverpool. Improvements in electric conduits and conductors therefor.*

13,795. W. P. THOMPSON. Liverpool. Improvements in the process of electro-plating and apparatus therefor. (Clarence Morse Barber, U.S.A.)*

July 18, 1894.

13,836. CHAS. G. YARNOLD. London. Improvements in apparatus employed in the evolution and collection of hydrogen and oxygen gases by electrolysis.

13,871. G. ANDERSON KELMAN, Senior. London. Improvements in or relating to electrical transformers or converters. (James A. Kelman, jun., U.S.A.).

13,872. GUSTAVE VERMEÉRE. London. Improvements in and relating to electric railways.

July 19, 1894.

13,900. A. M. ROSEBRUGH. Canada. An improvement in multiplex telephony. (Date applied for under Patents, &c., Act, 1893, Sec. 103, January 6, 1894, being date of application in U.S.A.)

13,903. CHARLES ELLAH STALLYBRASS. Cardiff. Improvements in magnetic locks or apparatus for opening locks of safety lamps by magnets only.*

July 20, 1894.

13,983. JOSEPH WADDINGTON. London. Improvements in apparatus for driving air propelling and exhausting ventilators electrically.

13,993. AUGUSTUS H. JOHNSTON. London. New or improved electric light regulator.

13,995. WILLIAM PHILLIPS THOMSON. Liverpool. Improvements in or relating to electric railways. (James Francis McLaughlin, U.S.A.)*

July 21, 1894.

14,029. STEPHEN SIMPSON. Mansfield. Improvements in prepayment mechanism, application to gas, electricity, and like meters.

14,065. W. A. MALSON, T. MALSON, S. R. MALSON, and EMMANUEL SMITH. London. Improved electric fuse head for use in blasting.

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price of 8d. each.

1893.

6,677. GRIMES. Railway electrical signalling devices.

13,779. MÖLLER. Telephone circuits.

14,000. DE FERRANTI. Electricity meters.

14,003. GOLDSTON. Electric circuit-closing devices.

14,481. MOY. Ammeters and voltmeters.

14,997. EDWARDS (La Cour). Electric contacts for telegraphic vibrators.

15,074. COOPER and others. Electric coupling.

15,355. PYNE and THOMPSON. Electric battery.

1894.

5,253. WISE (Lewis). Producing and utilising electricity.

5,254. WISE (Lewis). Producing and utilising electricity.

6,482. MOREAU and MUNIER. Telephone systems.

8,599. MCKEOWN. Electric arc lamps.

9,968. SPERRY. Arresting motion of electrically-propelled mechanisms.

10,045. ORMSBY and BANISTER. Electric motors.

10,169. BLOT. Secondary battery plates.

10,427. MEDHURST (Chandor). Composition for lamp incandescers.

COMPANIES' MEETINGS AND REPORTS.

Direct United States Cable Company (Limited).

The thirty-fourth ordinary general meeting of this Company was held at Winchester House, Old Broad-street, on Tuesday, under the presidency of Sir John Pender, G.C.M.G., M.P.

The SECRETARY (Mr. T. Finnis) having read the notice convening the meeting and the minutes of the last ordinary general meeting, which were confirmed, the report of the Directors was taken as read.

The CHAIRMAN then said: Gentlemen, I have no doubt that you have all perused the report carefully, but before asking you to approve it I will,

Digitized by Google

as usual, go over the heads of it, and make some reference to the conduct of the business during the last six months. The revenue for the half-year to June 30th last, after deducting outpayments, amounted, in round figures, to £34,843, and the working and other expenses, including income-tax, required £18,750, leaving a balance of £16,093 as the net profit of the half-year, making with £3,080 brought forward from the previous half-year a total of £19,173, which has been appropriated as follows: Interim dividend at 2s. per share for the quarter ended March 31st last, £6,071; final dividend of 2s. per share now proposed for the quarter to June 30th of £6,071; transferred to reserve fund account £6,000; balance proposed to be carried forward £1,031, making a total in round figures, as above, of £19,173. The revenue, as compared with that in the corresponding period of 1893, shows a falling-off of £5,993, which is attributable entirely to the prolonged commercial depression. The expenses in London, as shown by Abstract A in the accounts, remain practically unaltered as compared with the corresponding period. The expenses at stations, detailed in Abstract B in the accounts, show as follows: Increases of £70 in rent, taxes, fuel, and light, £112 in agencies, and £24 in assurance. On the other hand, however, there are the following reductions, namely, a small amount of £5 in salaries and wages, £40 in petty expenses, £83 in travelling, £35 in repairs, and £138 in printing and stationery. On the whole, these expenses show a reduction of £82. In the remaining items of expenditure there are reductions of £61 in storage of cable and £100 in depreciation, while the income-tax is increased by £44 owing to the higher rate now in force. The half-year's expenditure, in the aggregate, is less by £148 than it was in the same period of last year. The reserve fund has been increased by £4,184 interest on the investments, and by £6,000 transferred from revenue, and it now stands at £281 551. The investments have been increased during the half-year by £12,057, and now amount to £246,209 taken at cost. Their present market value shows an increase of about £32,500, or, say, 13 per cent. beyond cost. Now, gentlemen, these particulars do not show you that there has been any large increase of business during the last half-year; but I think you will remember that when I last addressed you I stated that the prospects then were not particularly bright. We were passing through probably one of the most severe commercial and financial crises that had ever happened in the United States, and I am sorry to say that the same condition of things prevails to day, although our past experience tells us that after a storm comes a calm, and after a calm there comes fine weather and brighter times. I have no doubt that that will be very much the result of our experience in our Atlantic system. The moment that trade begins to move there will be, no doubt, an increase in our traffic. The only thing is—and I am sorry to say it—that the preparations to meet that increased traffic are probably in excess of the requirements of the general traffic itself. We have just learned that one cable has been completed by the Commercial Company, and another is about to be completed by the Anglo-American Company, so that amid all these troubles there is no want of cable accommodation for carrying on the traffic. We hear rumours of another French cable being laid, and also rumours as to the possibility of a German cable being laid. I can give you no further information at present than that which the Press may have given you; but when the information does come, if it comes in such a form that it can be submitted to you, I shall be only too glad to submit it, and give you my opinion upon the opposition and the competition likely to arise from any addition to the cables in the Atlantic. You have heard, I daresay, that the suit in Paris has been finished; at all events, a decision has been given on it. It is said to be a favourable decision, but wherein the favour lies I have not yet been able to discover. I do not see that we shall get much, if anything, in return for the large sum we have spent upon it. However, we went into this under good advice—the Anglo-American Company acted under good advice in going into this suit; but if they get anything out of it I shall be only too pleased. Meantime, I do not see that the decision is likely to give us any real money return. The general working of our system has been fairly satisfactory. We had a small breakdown in Halifax Harbour, but it was very cleverly dealt with and repaired by our Manager there, with the assistance of some members of the Royal Engineers, who lent their aid with great readiness, for which I beg to thank them here before you all. They did good work in assisting us to effect that repair without our being obliged to send a special steamer to do it. We have had other little incidents and accidents, but all of very minor character; and, upon the whole, I may say that our half-year's working has been satisfactory in every respect except in that of earning power. We are, however, as I have said, short by several thousand pounds, and I attribute that entirely to the depression which has existed and which exists at the present time not only in America but also largely, as you know, all over the world. With these remarks, gentlemen, I beg to move the following resolution:—

"*That the report of the Directors, dated July 10, 1894, together with the statement of accounts to June 30th, 1894, annexed thereto, be and the same are hereby received and adopted, and that a final dividend be now declared of 2s. per share, free of income-tax, making, with the interim dividends already paid, a total dividend of 2⅝ per cent. for the year ended June 30, 1894.*"

Mr. E. M. UNDERDOWN, Q.C., seconded the resolution.

Mr. GRIFFITH expressed his satisfaction at hearing that the cable was in a fair condition, but he inquired whether there was any probability of their being compelled to lay a new cable within a short period.

The CHAIRMAN: I have often said that that was one of the factors in our position at the present time—the difficulty of being able to say how long the cable may "live"; but when a cable is getting towards twenty years old, it becomes those who are looking after it to see whether the time may not be approaching when it may be necessary to lay another cable. We have not yet taken that into consideration, because our combination with the Anglo-American and the Western Union Companies will enable us to live for a considerable time even if our cables were interrupted. But we have got a very good cable, as far as we can see, and looking at the repairs we have made in it and the considerable amount of new cable we have added to it, I hope that we may look forward for some years to a fair, moderate return on our present cable. Meantime we are not contemplating any serious expenditure upon a new cable. [He then put the motion, and declared it carried unanimously.] Continuing, he said: I think you will have observed—there has been a little general conversation about it—that while we have been obliged to reduce our dividend we are increasing our reserve fund. I am quite of opinion that with a large reserve fund we are placed in a very much sounder position, and I think it secures for the shareholders a better prospect of keeping their property at a fair price in the general market. I cannot, however, hide from myself the fact that we have a good deal of trouble before us in the Atlantic, but that is simply owing to there being more cables than are wanted for the work. There will be 12 cables in the Atlantic, and the scientific developments of the last few years enable us to carry just double the traffic that we did before the duplex invention was discovered. That is a fact which will give you an idea of the enormous carrying power which these cables possess. As I have said, I hope when the crisis passes away in America that there will be such a development of trade that a very large increase of traffic will result; and if that large increase of traffic comes, we may return to a better dividend than we are paying to-day.

Mr. UNDERDOWN, in moving the next resolution, said that on several previous occasions he had the pleasure of proposing the re-election of Sir John Pender, to whose list of honours another was added on the occasion of the brilliant fête a few days ago at the Imperial Institute. The King of Italy, recognising, as they all did, the enormous services which had been rendered to telegraphy by Sir John Pender, had signified that he had conferred on their Chairman the Great Cordon of the Crown of Italy with the Great Cross of that Order. He need not say that that was a very great honour in itself, as manifesting the international appreciation of Sir John Pender's great services. He was sure that they all hoped with him (the speaker) that that would not be the last of the acts of appreciation which their Chairman would receive, and which he deserved, not only from this country but from the colonies, and in fact, from all who were connected with the commerce and communications of the world. It was a very great pleasure to him personally to be present at the Imperial Institute, when one of the most brilliant assemblages seen for a long time came together. He wished that the same harmony that prevailed at their Board existed among the rivals of telegraphic enterprise, in which case there would not have been such haste to lay so many cables in the Atlantic, and everyone would then probably have fared better.

Admiral of the Fleet the Hon Sir HENRY KEPPEL, G.C.B., D.C.L., in seconding the motion, said he could endorse everything that had fallen from Mr. Underdown.

The resolution was carried unanimously.

Mr. UNDERDOWN afterwards proposed the re-election of Mr. James Pender, observing that that gentleman worthily filled a regretted vacancy on their Board, of which he was a most admirable member from his knowledge of the business.

Mr. C. E. GUNTHER seconded the motion, which was unanimously carried.

The CHAIRMAN: In regard to myself, the very kind words which have been used by my old friend and colleague, Mr. Underdown, are very gratifying to me. The honours which have been conferred upon me from time to time I have always accepted as an evidence of the inestimable good which submarine telegraphy has conferred upon humanity. It has been a marked success, and has enormously benefited the commerce of the world, and been a great advantage to it in a political sense. I think that all those who have taken part in it, either as shareholders or in any other way, have reason to be proud of the outcome of this great invention. I hope I may be spared for some time still to carry on this good work, in which I feel the very deepest interest. The past has been, I would say, very successful, and let us hope that the future will be still more successful. In that case I shall feel that I have done my duty to you and to the country at large, and have aided in building up that prosperity which has kept England at the top of the commercial ladder, where I hope it will remain for a long time to come. I beg to thank you again for the honour you have done me in re-electing me.

Mr. W. GRIFFITH, who referred to the excellent way in which the Company's books were kept, proposed the election of Messrs. Deloitte, Dever, Griffiths and Co., and Messrs. J. & J. Sawyer and Co., as auditors for the ensuing year.

The motion was seconded, and unanimously adopted.

Mr. W. GRIFFITH then proposed a vote of thanks to the Chairman and Directors for their able administration of the Company's affairs.

Mr. JOHN NEWTON seconded the motion, which was unanimously adopted.

The CHAIRMAN: I beg to thank you on behalf of myself and colleagues. We get on uncommonly well together. We watch as closely as we possibly can the state of business, and when things are good we rejoice, because we know it will gladden all your hearts; while when things are depressed, we feel regret because we know the state of things is not quite satisfactory to those whose support we crave. Nevertheless, we have to take these ups and downs. We keep your business in a very sound and safe state, however. You see in the reports we present to you how carefully your affairs are dealt with; and I think that our auditors will testify to the fact that our accounts will bear very close inspection indeed. That is what we desire. We feel that, after all, in these times, good book-keeping is a great necessity; in fact, through the absence of good book-keeping there has been more trouble in London in the last few years than one cares to contemplate, and sorrow has thus been brought to many homes. You will have no trouble with respect to our accounts, which "those that run

Digitized by Google

may read." I hope that that will always be the case, and if you find us in any way going back in that matter, I hope there will be men among you who will not hesitate to call attention to it. If any fault is pointed out you may depend upon it that we shall only be too happy to remedy it. I thank you very much.

The proceedings then terminated.

United River Plate Telephone Company (Limited).

The following is the report of the Directors of this Company for the year ended March 31st last, which will be presented to the shareholders at the eighth ordinary general meeting, to be held at Winchester House, E.C., on Friday next, at 12 o'clock :—

At par of exchange the gross receipts for the year were £134,076. 15s. 10d., the working expenses in the River Plate £60,874. 0s. 3d., and the loss on exchange £54,124. 17s. 9d., leaving a profit, after the deduction of debenture interest and all other London charges, of £9,782. 4s. 4d. It is proposed to write off £500 against bad and doubtful debts, £500 against the Mendoza Land, £270 premium on the balance of the Seven per Cent. Debenture Bonds paid off, and to transfer to depreciation and renewal fund £3,000, leaving a net balance of £5,512. 4s. 4d. This sum, increased by £905. 13s. (the balance brought forward from last year's account), amounts to £6,417. 17s. 4d., which has been carried forward. The capital outlay for the year was £3,038. 5s. 8d., as against £3,394. 10s. 9d. for the previous year. The plant has been maintained in good and efficient condition at the cost of revenue. Notwithstanding the considerable and unexpected rise in the gold premium, the business of the Company has steadily improved during the year. The Directors feel confident that the shareholders, in view of the continued uncertainty in the affairs of the River Plate, will approve of the action of the Board in carrying forward a substantial balance to strengthen the financial position of the Company.

Mr. J. Irving Courtenay and Mr. George Cooper retire, and, being eligible, offer themselves for re-election as Directors, and Messrs. Cooper Brothers and Co. offer themselves for re-election as auditors.

National Telephone Company (Limited).

The fourteenth annual ordinary general meeting of this Company was held on Wednesday, at Cannon-street Hotel, Mr. James Staats Forbes (President) presiding.

The SECRETARY (Mr. Albert Anns) read the notice convening the meeting.

The CHAIRMAN: I should like to begin by calling the attention of the proprietors to the number of gentlemen interested in the undertaking. At the date of closing the books there were 7,159 holders of shares, and 1,700 holders of debentures, making a total of 8,859 individuals interested in the Company, showing a very wholesome increase upon the figures of last year. A comparison of 14 months—for that is the period covered by the report—with 12 months, involves a good deal of mental arithmetic which you will find it difficult to follow : and in order to prepare you for a real comparison we have appended to the report an extremely useful table called an abstract of accounts. The reason why we are dealing with 14 months instead of 12 months is, as most of you know, because we have decided to hold half-yearly meetings, and in order to bring our financial year into line with the calendar year we have had to make the accounts up to June 30th instead of April 30th. But for the purpose of being able to clearly see what progress we have made we have, in the abstract to which I have referred, divided the sum total with which we have to deal for the 14 months into the 12 months ending April 30th, and the two months from April 30th to June 30th. As the report shows the accounts up to April 30th have all been audited and ascertained. That is equally true of those for May, but as our desire was to hold this meeting as nearly as possible at the regular date we had to estimate the results for June. We were careful to make that estimate a safe one by fixing the amounts well within what we believe they will prove to be. I will now turn to the abstract of the accounts, for the purpose of making a comparison of twelve months with twelve months. You will see by that abstract that the income accrued in respect of the business of the year ending April 30, 1894, was £682,950, against £583,590 in the year ending April 30, 1893, or an increase of about £100,000. Then the working expenses and other charges, excluding debenture and other interest—in fact, the cost of working the undertaking as a going concern—was £311,644 in the year ending April 30, 1893, as compared with £344,168 in the year ending April 30, 1894, leaving a balance of £338,781, against £271,945 for the year ending April 30th, 1893. You will see that that sum of £338,781 is subjected to a rather large deduction in the shape of Post Office royalties. You know we hold a license on the conditions that we pay to the Post Office 10 per cent. of all the gross receipts arising from that part of our business which is called exchange business. In respect of what are called private wires, we are free from this tax. It is an enormous tax that we have to pay the Post Office. For the 12 months in question it comes to £63,254, or something like 2½ per cent. on the ordinary shares. Deducting that amount, it brings the net result for the year which we can appropriate to our own purposes to £275,526 as compared with £217,725, the net result of the preceding year. Now, what becomes of this sum? You will see that for debenture and other interest £48,266 is required, against £40,646 in 1893, and the money needed to pay the dividend we propose for 1894 is £168,957, against £149,367 in the previous year, and then we carry forward £60,496 against £32,000 in the preceding twelve months. The last item in the abstract of accounts is not the least satisfactory. It is that of rentals carried forward for unexpired terms, and it shows that the amount for the year ending April 30th last is £334,985 against £285,020 in the corresponding period. It comes, in fact, to this, that we have in our pockets already £50,000 more money in respect of subscriptions than in the previous year. The report gives the amounts for the 14 months, whereas the figures I have just put before you were for 12 months, in order to show you by comparison with the corresponding figures in the previous year the headway made by the Company. Out of the available balance of £262,311 for the 14 months shown by the net revenue account, an interim dividend at the rate of 6 per cent. per annum on the First and Second Preference Shares, and 5 per cent. on the Third Preference and Ordinary Shares has already been paid. By the next day, if you endorse the recommendation of the Board, you will be in possession of dividend warrants for a further dividend of £3. 6s. 8d., £2. 10s. of which will be for the second six months and the 16s. 8d. for the two months we have brought into these accounts, May and June. When we meet next time it will be a six months' account from June to December, and so on according to the calendar from half-year to half-year. Out of the surplus, the Board proposes to transfer £63,429 to the reserve fund, so as to bring it up to £225,000, and to carry forward £1,765. I think it is wise that proprietors should be fully informed with reference to the capital account, and I will therefore say a few words on this point. You will recollect that last year I explained that for every additional subscriber the capital expenditure was about £42. This year it was somewhat less, but if you multiply £42 by an appreciable number, suppose we say 10,000, and that goes on, as it does, from year to year, it means that every year, in order to get a larger income, we must put down large sums of ready money to provide the necessary extensions of machinery. If you look to the capital account you will see that the expenditure stands thus, as per last account, £4,023,021. During the period under review we have spent on land, buildings, and machinery £33,260 : on the purchase of the Telephone Company of Ireland (Limited) and the Home Telephone Company (Limited) £101,039 : and on construction of exchange, trunk and private lines, &c., £306,006, making a total of £4,463,327. You may take it that the capital expenditure for the purchase of other undertakings is now practically at an end. The responsibility of spending such large sums of money rests with the Board, but men who fill positions of this sort must have the courage of their convictions, and act on their best judgment, and that we do scrupulously ; and I might almost say religiously, but perhaps it is better not to drag religion in. It must at least be very satisfactory to the proprietors to find that the money we have spent has been immediately profitable. Paragraphs 9 and 10 of the report are, I think, of general interest. In paragraph 9 you are informed of the position in which we now stand with the Post Office in respect of the agreement under which we have undertaken to hand over to them the trunk lines of the Company while we continue the Exchange business. It is difficult for us on this side of the table to see the advantage of carrying on the business under two umbrellas instead of one, but we were in the position of having to agree to the arrangement, not because we liked it, but because we could not help ourselves. It is very easy to draw up the heads of an agreement and to express them in simple language, but I hope I shall not be wounding the susceptibility of any lawyer in the room if I say that lawyers have a happy knack of clouding simple phrases with dark interpretations. Therefore, it has taken two years to find out what those heads of agreement meant, because when you come to details in a business like this, made up of two factors—the known, and largely the unknown—it is difficult to deal with them. I am bound to say that the Postmaster-General and all the officials downwards have shown great regard for fair action in the matter. Happily we have now come to a conclusion in this affair, and the Postmaster-General is, I believe, now free to submit this agreement to the confirmation of the House of Commons. We, of course, are advised that the agreement is already in existence, having been signed two years ago on behalf of the Government, and this Company, and I can apprehend no such possibility as any serious objection being raised on the agreement itself by the House of Commons. Therefore, I suppose, very shortly we shall move on the new lines. What the result will be what man can foretell? We cannot. But if there are difficulties to be overcome there is only one way to overcome them. This is a Company which must be worked in the interest of the public first and then of the proprietors, and it is our duty to make the telephone service of this country the best in the world, and there will be neither skill nor money wanting on our part to achieve that result. I am sure you will be glad to hear, as stated in paragraph 10, that we are carrying out the redemption of our existing debenture debt. It seems fortunate that the Money Market has remained so long in a state to make it possible to convert that debt from Four and a-Half per Cent. Debenture Stock to Three and a-Half per Cent. Debenture Stock. It is done, of course, at some sacrifice, because we have had to redeem it at 110 ; but when it is completed the saving of 1 per cent. in interest on a million of capital will be of great importance. As you will see by the report, four of the Directors retire, and, being eligible, offer themselves for re-election. Without saying anything further I will now move :—

"That the report and accounts be received and adopted, and that dividends be paid for the eight months ending June 30th last year, at the rate of 6 per cent. per annum, less income-tax, on the First and Second Preference shares ; 5 per cent. per annum, less income-tax, on the Third Preference and Ordinary shares ; making, with the interim dividend paid on December 22, 1893, a dividend at the rate of 6 per cent. per annum on the First and Second Preference shares, and 5 per cent. per annum on the Third Preference and Ordinary shares, for the fourteen months ending June 30, 1894."

Lord BALFOUR of BURLEIGH, in seconding the resolution, said his connection with the Company during the past year had confirmed the

Digitized by Google

favourable opinion he expressed at the last meeting as to the manner in which the business was carried on, and the prospects awaiting the Company. The question of giving an efficient service to London had specially engaged the attention of the Board during the past year, and he thought he was entitled to say there never had been a time when the efficiency of the service in London was as satisfactory as at the present time. He believed it had been greatly improved during the last 12 months, and it would be the continuous effort of the Board to improve it as much as possible. They frequently saw in the papers complaints from people who were subscribers to the telephone in London. In his opinion they could hardly make a fair comparison between London and other communities, on account of its size and the concentration of business in one part. If they could show that the telephone service given in London, with all these difficulties, was provided at a rate not only as reasonable, but more reasonable than in many other communities where the service might be expected to be cheaper, he thought they would have made a point to the credit of the Company. Now he took the first four cities in America, and he found that in New York the annual payment was £56, in Boston £37, in Chicago £25, and in Philadelphia £25—in every case considerably higher than the charge in this metropolis. Looking on the Continent of Europe he found that in Paris the charge was £16, without instruments, which might be taken as adding 40s. to that sum. He believed that outside critics often failed to make sure that they were comparing like with like in making their comparisons. In St. Petersburg the annual charge was £39. 11s., and the same in Moscow, and in these places on the Continent, if he were rightly informed, there were no royalties to be taken into account. He desired to endorse the statement of the Chairman that it would be their desire to assist the Post Office in working under the new arrangement. It struck him that as partners with the Post Office they would come into contact most with the customers, and, therefore, if anything went wrong receive all the censure. If they were to receive criticism, he hoped it would not be forgotten that there were two partners to the business, and that it did not follow that the one readiest to hand deserved it most. It was possible they might deserve some criticism, but he hoped it would be divided fairly.

Mr. GALBRAITH called attention to the letter written by the Postmaster-General on the 6th inst. to Mr. Henniker Heaton, M.P., in which he said: "On the termination of the license in December, 1911, the right of the National Telephone Company to carry on telephone exchange business will cease. All they will have to sell will be their plant, and even this the Government will be under no obligation to buy." He should like to hear what the Chairman's views were with regard to that communication. Alluding to the reserve fund, he urged that it should be invested in Consols, and be available for the equalisation of dividends amongst other purposes.

The CHAIRMAN, in reply, said: The answer of Mr. Arnold Morley to Mr. Henniker Heaton is literally true, but there are some truths which are a good deal qualified by considerations and circumstances. The statement that all we shall have to sell will be our plant is not true in fact. Mr. Arnold Morley, when he wrote this letter, believed it was; but he did not consider the fact that a large portion of our profit is made on private wire business, which is a growing quantity. At the end of eighteen years, which our lease has to run, if we know our business and play our game properly, that business will be a hard nut for the Post Office of the day to crack. Possibly by 1911 it will be worth £200,000 a year. That would be something to sell. But there was something else. Long before then the Government will have to make up their minds whether they will take over the exchange business. If they decided in the affirmative what will be the rational course for them to pursue? Will they six, or even ten years before the moment arrives, embark upon the enormous expenditure of erecting machinery and plant to supersede that belonging to our Company for the purpose of knocking down the price of our business? The idea is so reckless that one cannot believe it will enter into the mind of any responsible person. I do not believe that a great public department like the Post Office will be so lost to a sense of their duty to the taxpayer, and of fairness to this Company as to spend huge sums of money in order to confiscate our property. In reply to Mr. Galbraith's question about investing the reserve fund in Consols I may say that now that we can borrow money at 3½ per cent., instead of 4½ per cent., as formerly, the objection to putting our reserve fund into Consols has to some extent vanished. The feeling of the Board is inclined very much to the desirability of doing so, sooner or later, probably sooner than later, but we want to see our way out of this Post Office affair first.

Mr. LEAK and Dr. GALE having made a few remarks, the resolution was carried.

On the motion of the CHAIRMAN, seconded by Lord BALFOUR of BURLEIGH, resolutions were passed making the necessary alterations in the Articles of Association in view of the intention of the Board to hold half-yearly meetings.

Mr. G. Franklin, Mr. W. Cuthbert Quilter, M.P., Mr. W. A. Smith, and Mr. Alderman Joseph Thompson were then re-elected as Directors; and Messrs. Welton, Jones and Co. were reappointed auditors.

A vote of thanks to the Chairman terminated the proceedings.

Edison and Swan United Electric Light Company (Limited.)

The annual meeting of this Company was held on Thursday, at Cannon-street Hotel, Mr. James Staats Forbes (Chairman of the Directors) presiding.

The SECRETARY (Mr. H. Charles Gover) read the notice calling the meeting.

The CHAIRMAN said: This is rather an interesting meeting, as being a new departure. Either by being present at the meeting or reading the proceedings, the proprietors of the Swan and Edison and Swan Companies are familiar with what has recently taken place. As from October 1st, I believe it was, of last year the United business came into operation, and the accounts now before you embrace that united business as from that date. By looking at the accounts you will see what the result is. There is very little to be read in the report itself beyond the mere fact that such and such things have been done, and the Companies have been fused wholly instead of partially; that interest has accrued upon the £100,000 Debenture Stock for three-quarters of a year under the agreement; and that the whole of the assets and business of the Swan Company outside England has been handed over; and certain particulars as to the first result of the United Company. It is a new departure also in the sense that having emerged from the shelter and protection of our patents we are now in open competition. We have a great many extremely keen rivals, and it seems, to us at all events, prudent that we should follow the example of ordinary traders and keep a good deal of our knowledge to ourselves. I daresay there are a great many people, interested parties, who would very much like to know what our business is, where it is, where our customers are, and where we make our profits. We do not think it expedient to reveal that information to them. I do not know whether that will be your feeling. It is ours, very strongly. The accounts reveal a good deal, but they only show general results; and I propose, with your permission, to go through them, and dwell upon one or two of the most salient points. First of all, I must remind you that the present position and outcrop has been anticipated for some time. At the last meeting, about twelve months ago, I had occasion to forewarn you of what would arise when our patents expired in November, that of necessity it must be followed by a large reduction in the price of the lamp. As you know, during the period our patents ran we were entitled to try and get back in the shape of dividends what money our patents had cost us. In a certain sense it has come back, although not quite in the degree which might have been anticipated. We paid off all the arrears due to the "A" shareholders, the 7 per cent. accumulated over a term of years, and we carried forward a balance for the benefit of the united concern in the future, and we have now taken over the whole of the stocks of the other Company. The profit and loss account will reveal where we are. You must bear in mind that there is a great difference between 2s. 9d. or 3s. for a lamp and 1s. The cost of production nor of administration diminishes, and therefore what we have to look forward to is the character of our lamp, and large connection; the admirable appliances we have at hand, and, amongst other things, our very large stock. As far as it goes that is the protection of this Company now. We have ascertained beyond question that the types of lamps are so numerous, and the gradations of quality are so nice and subtle that a very large stock of lamps must be kept in hand to supply all our customers. One man wants a lamp to be fixed subject to a current of a certain pressure at one part of a building, or at a diminished or increased pressure of current somewhere else, and that means the adaptation of the lamp to the pressure which reaches it. If the lamps are put in the wrong place they perish rapidly. All that is a matter which our experience has evolved, and we have had to lay ourselves out for it, but this in itself gives us a distinct advantage over any small manufacturer. In fact a small manufacturer cannot live at it, because to compete with us he is obliged to lock up in plant and stock £127,000, that being the figure which you see our plant and stock stands at in the balance-sheet. That figure represents not only lamps but platinum and other material on a large scale. We have established two depots in London and ten in other places, making twelve in all. Each of these places has to be furnished with a stock of all kinds of lamps and fittings to be at the disposal of anyone who likes to go in to inspect them and give an order. The stock on hand on July 1, 1893, was £63,349, and you will see, on the opposite side of the profit and loss account, that on June 30, 1894—that is, at the termination of the book year—it had risen to £87,768. That increase arises from the fact that we have taken over the stock of the Swan Company, part of the purchase for £100,000 of their residuum and their going business. Then, as you will find by the account, there are the items for wages, purchases, &c., for £102,599; salaries, Directors' remuneration, rent, office expenses, insurance, income-tax, general and law charges, £11,651; and depreciation on plant, &c., £9,451, leaving a balance of £34,400. This balance is the difference between the value of the stock and the costs incurred in production to keep the stock up to replace sales during the year. On the other side of the account you will see that the returns by the sale of lamps, fittings, royalty on holders and interest, &c., amount together to £133,663. The share account stands pretty much as it did last year, with the addition to the balance sheet of £100,000 Four and a-Half per Cent. Debenture Stock—the purchase price of the Swan residuum. The reserve fund stands at £72,760, and the sundry credit balances, which is a floating quantity, at £26,269, against debtors on the other side of the balance-sheet amounting to £40,970. After deducting from the balance of £34,400 the sum required to pay the interim dividend paid on March 20, 1894, there remains £25,563. From the statement showing the proposed appropriation of payments, you will observe that to payment due on Four and a-Half per Cent. Debenture stocks for the nine months ended June 30, 1894, £3,375 is appropriated; for the payment of an interim dividend of 5 per cent. per annum on the "A" shares for the half-year ended December 31, 1893, £8,836; to the payment of a dividend of 7 per cent. per annum for the half year ended June 30, 1894, £12,371; and to the reserve fund, £9,816. During a portion of the past year we were working we were still protected, and the money benefit of that was between £16,000 and £17,000. We are not afraid of competition. So far we have managed to hold our own, notwithstanding the eagerness

Digitized by Google

with which lamps were pressed into England from different places in anticipation of our patents running out. We have sold about the same quantity of lamps as we did before competition commenced, and we have obtained a price for them somewhat in excess of that which our competitors got, because we have a character as well as a lamp. There was a marked depreciation in the profit per lamp, but we hope to make up for that by increased sales as the development of the trade goes on, as no doubt it will. I need scarcely point out that two millions of lamps sold at a particular profit will produce as much dividend as a million sold at a larger profit. That is what we have to rest upon, and without, of course, being too prophetic or wishing to excite undue hopes, I think I may say we know enough of this business now to justify the conviction which we feel that this is a sound commercial business, with a good future before it. We could easily have paid a 7 per cent. dividend for the year, but we thought it more prudent to start as we hope to go on. If in the coming time the profits should increase to such an extent as to justify a larger dividend, we shall have the opportunity of taking your advice upon the subject. It might, perhaps, be prudent a little further on to apply a portion of our profits from year to year to the redemption of some of our capital, but that is a matter not immediately concerning us at present. We have some investments, more or less good, brought into this balance-sheet for the first time, namely, the shares in La Compagnie Générale des Lampes Incandescentes, £30,489. They may be worth more, but it is certain that they will not be worth less, because at the end of this year we have the option of going on in that Company, or giving it up, and by liquidation or arrangement recovering our portion of the value of the asset. We have made up our mind, and have communicated our feeling to the proper quarter, that it will be much better for us to be free all over Europe to sell lamps than to remain partners in this French Company, subject to the existing condition that we shall sell no lamps on the Continent except in Germany. You will see what that means. Supposing there should be a small sacrifice on the capital as it stands, in the liquidation or arrangement, we should recover our freedom for the sale of lamps over the whole of Europe as a compensation, and as we believe with our appliances we can produce lamps in large quantities in London more cheaply than they can be manufactured even in Germany, I think we shall have a good chance of establishing a big export trade. Then in addition to £40,912 in freehold property we have an investment of £25,000 in the National Telephone Company, Five per Cent. Non-cumulative Third Preference Shares. Happily these shares are now at a premium, and instead of £25,000, which the shares cost, they are now worth £27,000. Then there is cash in bankers and in hand £39,360, a considerable portion of which, after paying the dividend we now recommend, we propose to invest in some substantial security. I will now move:—

"*That the reports and accounts for the year ending June 30, 1894, be received and adopted.*"

Major FLOOD PAGE (Deputy Chairman) seconded the motion, and remarked that owing to the improved condition of their business requiring more space than they had in Victoria-street, the Company would be moving into Queen-street, Cheapside, in the course of the next few weeks.

The motion was agreed to unanimously.

The CHAIRMAN then proposed :—

"*That a dividend be, and is hereby declared on the "A" Shares of the Company, of 2s. 1¾d. per share on the 89,261 Ordinary Shares, £3 paid; of 3s. 6¾d. per share on the 5,000 £5 fully-paid shares allotted to the Edison Electric Light Company (Limited); and of 3s. 1¾d. per share on the 12,139 £5 fully-paid shares allotted to the Swan United Electric Light Company (Limited); being together with the interim dividend paid on March 20, 1894, 6 per cent. in respect of the year ending June 30, 1894. All to be distributed in accordance with the provisions of Clause 87 of the Articles of Association; less Income-tax.*"

Major FLOOD PAGE seconded the resolution.

A SHAREHOLDER inquired whether as a Swan shareholder he participated in the present dividend?

The CHAIRMAN: You are a shareholder in the Edison and Swan Company, because as a Swan shareholder you hold 60 per cent. of its capital, or rather your Directors hold it for you. It acts individually in this way: You are also now, in virtue of the recent agreement, entitled to a portion of the £100,000 Debenture Stock which has been paid for the residuum of your property not included in the Edison and Swan Company previously, and when matters are in order you will receive, not Swan shares—they will be cancelled—but shares in the Edison and Swan proportionate to your holding, plus your proportion of the £100,000 of debentures, plus the dividend.

The resolution was unanimously carried.

Major FLOOD PAGE then moved, and the EARL of LICHFIELD seconded, the re-election, as a Director, of the Chairman, which was agreed to with acclamation.

On the motion of Mr. DEED, seconded by Mr. J. W. SWAN, Messrs. Welton, Jones and Co. were reappointed Auditors.

The following is the Directors' report above referred to:—

In accordance with the agreement entered into with the Swan United Electric Light Company (Limited) the foreign business and assets of the Swan United Company have been taken over as from October 1, 1893, and the accounts now presented include such business and assets, in addition to the British business of the Edison and Swan Company itself. After providing for the interest accrued upon the £100,000 Debenture Stock there remains a balance of £31,025. 3s. 3d. available for distribution on the share capital. The Directors recommend the payment of a dividend as follows (less income-tax):—On the 89,261 Ordinary shares, 2s. 4¾d. per share; on the 12,130 fully-paid "A" shares, allotted to the Swan United Company, 3s. 1¾d. per share; on the 5,000 fully-paid "A" shares allotted to the Edison Company, 3s. 6¾d. per share. This distribution, together with the interim payment already made in respect to the first half-year, make up 6 per cent. for the entire year. Warrants will be posted on August 3rd.

The business of the Company, thus united, has resulted in a credit balance of £34,400. 3s. 3d.; of this, £8,856. 19s. was distributed on March 20th last, as an interim payment on the "A" shares. The Directors recommend a further distribution of £12,371. 14s. 7d. on the "A" shares. This, with £3,375 interest on debenture stock, will absorb £24,583 13s. 7d., leaving £9,816. 9s. 8d., which the Directors have carried to the reserve fund. The Directors consider the result as satisfactory, and also that the volume of business has increased during the year, in the face of active opposition in the lamp business since the expiration of the key patent in November last. The diminution of the money value of the sales is entirely due to the serious reduction in the price of the lamp.

Telegraph Construction and Maintenance Company (Limited).

In accordance with the resolution of the general meeting of February 28, 1871, a half-yearly general meeting of this Company was held at 38, Old Broad-street, on Tuesday, under the presidency of Admiral Sir G. H. Richards, K.C.B.

The MANAGING DIRECTOR (Mr. William Shuter) read the notice calling the meeting.

The CHAIRMAN: Gentlemen, your are aware, I know, that at these half-yearly meetings we do not produce any accounts to you. In point of fact, there is really no business of the Company to be transacted, but at the same time we are exceedingly happy to meet you and to tell you anything that may be of interest in connection with the prospects of the Company for the present year. In the first place, as you know, we have declared a dividend of 10 per cent. for the half-year, or 12s. per share. In regard to the work that we have done in the past half-year, it has been a very large amount, and we are quite satisfied ourselves with it, and therefore hope that you will be. I may say that we have laid a cable from Singapore viâ Borneo to Hong Kong in China. That is a long cable. We did this work for the Eastern Extension Company at the beginning of the year by two of our ships. Since then we have manufactured an Atlantic cable for the Anglo-American Company, a cable between Ireland and Newfoundland; and at the present moment our ships are engaged in laying it, and I hope that in the course of a few days this will be successfully accomplished. That is a very fair amount of work, as you may know. In a Company like this we cannot give you any correct information as to what we may do for the remainder of the year. Sometimes we do all our work in the first half-year, sometimes we do it all in the last half, and sometimes our work extends throughout the year. We manufacture things which are not of every-day use, and it is impossible to say what we may do for the rest of the year. We cannot tell you unless we have a contract signed, or otherwise it would be mere prophecy, and I do not think it would be right for the Directors to commit themselves to what may be an uncertainty. There are certain risks in this Company, but hitherto we have been very fortunate, and have been able generally at the end of the year to give you good accounts in our reports. I have every reason to hope that we shall give you a good statement this year. I am very pleased to be able to inform you that we have done so much in the past half-year, for which, I repeat, we are satisfied, and as I have said, I hope that you will be. I do not know that I can add anything further, but if you have any questions to ask me I shall be very glad to answer them.

Mr. CROFT: I have been a shareholder in this Company for a great many years—a great many more years than I care to remember, and I am sure that the announcement you have made to-day will be regarded as very satisfactory. In saying this I feel that I am only expressing the views of all the shareholders, not only of those who are present, but also of those who are absent. As I say, I have been a shareholder for a great many years, and I have never said or done anything which could in any way embarrass the Directors of this Company. On the contrary, I have on several occasions, I hope, supported the policy of the Board when it has been somewhat adversely criticised by the shareholders. There is, however, one subject to which I desire to allude to-day. It is a somewhat painful one; but I feel it my duty, nevertheless, to refer to it. I had intended to bring it forward at the last meeting in March, when there would have been a fuller meeting of the shareholders, but I was unable to do so, and I am now glad of it, because since then matters have developed themselves in a rather startling form, I might say. The matter I allude to is this: I hold in my hand the original prospectus of a company which has become notorious of late, and into the conduct of the Directors of which an investigation is at the present time going on. In the prospectus I find the name of one of your Board, whose name is paraded as Vice-Chairman of this Company. That gentleman has been examined on oath, and has stated that he is not related to any of the gentlemen whose names have been so notoriously connected with that Company. I therefore most loyally and cordially accept that statement; but it is a very curious coincidence, no doubt, and must have struck many others besides myself. What I do say, however, is that his name has been paraded in that prospectus, which was issued to the public, and among others to myself, and I was greatly influenced in taking shares in that Company by seeing the name of that gentleman published in the prospectus. His name appeared as Vice-Chairman of this Company—a Company which everyone will admit is one of the most successful in the City of London. When a member of another Board is put forth in that way the only object of it could be to attract the public, and to say, Here is a gentlemen who is going to act on this Company who is already the Vice-Chairman of one of the most successful companies in the City of London. What I say is, that

Digitized by Google

gentlemen ought to be very careful indeed when they allow their names to be used in this way. As I said, I was myself influenced in taking shares in that Company by seeing that the name of the gentleman to whom I am alluding was connected with it. You might say that I ought to have made more careful inquiries, and the profession to which I belong does induce caution; but we have seen in this very case that there was another gentleman belonging to the same profession who was attracted in a similar manner. I think that many would be influenced as much as anything as by the fact of seeing the name of the gentleman who is the Vice-Chairman of this Company put forth as a Director of that Company. Probably the hon. gentleman himself regrets his connection with that Company, perhaps no one more than he. I acquit him of any sort of mismanagement of that Company. I believe that he left the management, as the other Directors did, to one gentleman, who I believe is solely responsible for what has happened. I trust that in the future no gentleman will allow his name to be put forward in this way without duly considering what the effect may be upon the public, because it is really a very serious thing indeed.

The CHAIRMAN: I am sure we are here all perfectly satisfied as to the part which Mr. Rawson has played in this matter; but I am sure that you would like him to explain it himself.

Mr. P. RAWSON: I do not propose to enter into any long explanation. I am quite ready to admit that I am heartily ashamed of any connection I have ever had with the Company referred to. I originally lent money to the particular gentleman to whom you allude, and I was persuaded to look after my own interests, feeling that while I was doing so I was also looking after the interests of others. The result has been what you know. I have lost a considerable sum of money, and am as great a sufferer as anyone. I may say that I am perfectly sure that not a single member of the Board of that Company has profited to the extent of a shilling as a Director of it. The examination is going on to-day, and I believe it will be for the last time; and I hope it will be found that we are all acquitted of having done anything contrary to the strictest integrity. I left the Company some time ago. I did not like what I saw going on, and it is more than two years ago since I withdrew from it, and I withdrew on the score of not having sufficient information laid before me.

The CHAIRMAN: I do not think we have anything more to tell you, and I am very glad that we have been able to tell you what we have done on the present occasion.

Mr. CROFT: Before we part I propose a vote of thanks to you and your colleagues for the successful way in which you have conducted the affairs of the Company.

Mr. THORNTON: I will second that.

The motion was unanimously carried.

The CHAIRMAN: Gentlemen, I thank you very much for your kindness. We appreciate your thanks very much. We have done our best to earn them, and we shall continue to do so.

The proceedings then terminated.

Globe Telegraph and Trust Company (Limited).

The following is the Directors' report to be presented to the twenty-first ordinary general meeting, to be held at Room 174, Winchester House, Old Broad-street, E.C., to-morrow (Friday), the 27th inst., at 1 p.m.:—

The net revenue of the Company for the year ended July 18, 1894, after deduction of expenses, amounts to £185,076. 13s. 9d., and makes, with the balance of £1,304. 17s. 9d. brought forward, a total of £186,381. 11s. 6d. From this amount there has been distributed the sum of £125,955. 16s. 1d. in interim dividends, leaving an available balance of £60,425. 15s. 5d. The Directors recommend the payment of a final dividend for the year of 3s. per share on the Preference shares, and of 3s. 9d. per share on the Ordinary shares, making, with the previous distributions, a total dividend for the year of 6 per cent., less income-tax, upon the Preference, and 4½ per cent. net (against 4⅝ per cent. for the preceding year) upon the Ordinary shares, and carrying forward a balance of £527. 2s. 4d.

The £62,000 Six per Cent. Debentures of the Direct Spanish Telegraph Company which were held by this Company, matured May 1st last, and were paid off. Part of this money, viz., £16,989. 1s. 9d., has already been invested as follows:—300 shares in the Western Union Telegraph Company, 250 shares in the American Cable Company, 22 certificates in the Submarine Cables Trust, 354 Ordinary shares in the Direct Spanish Telegraph Company, 346 Preference shares in the Direct Spanish Telegraph Company. The remainder will be reinvested in suitable securities.

In conformity with the Articles of Association, Lord Sackville A. Cecil and the Marquis of Tweeddale, two of the Directors, retire, and, being eligible, offer themselves for re-election; as also do the auditors, Messrs. Deloitte, Dever, Griffiths and Co., and Mr. William Griffith, B.A.

Chili Telephone Company (Limited).

The Directors' report to be submitted to the annual general meeting to be held at Winchester House, London, E.C., on Tuesday, the 31st inst., at 11.30 a.m., is as follows:—

The small addition to the tariff made towards the end of 1893 caused some subscribers to withdraw, but others have taken their places, so that the aggregate in all centres was 3,987 at the end of the year 1893-94, only 37 less than at the beginning of that year. By this increase of rates the revenue has been augmented, notwithstanding the smaller number of subscribers. The income for the year was $504,188, and that of the former year $448,661—increase $55,527. The further depreciation in the sterling value of the currency, in which the Company is paid—from 18d. per $ in 1892-93 to about 14d. for the subsequent year—has deprived the Company of all benefit from this increase of revenue. It has also increased the outgoings—many more dollars having to be given for the same services; hence the net income was—For the year 1892-93, $184,673; for the year 1893-94, $179,652—decrease, $5,021. In sterling the diminution of net income is more marked, being—At 18d. per $ in 1892-93, £13,850; and at 13·96d. per $ in 1893-94, £10,448—decrease in net income, £3,402. From this net income of £10,448 the interest on debentures and other expenditure in London are deducted, amounting to £4,943, which varies little from the aggregate of similar items in the previous year. The loss by the reduction of exchange in the sterling value of the liquid assets and liabilities in Chili amounted to £1,979, being less by £1,616 than the corresponding item in the former year. The net profit of the whole business was: In 1892-3, £5,393; in 1893-4, £3,528; diminution, £1,865. This net profit of £3,528 has been added to the reserve fund. The cash is not available for distribution, having been used for capital purposes instead of raising that sum by the issue of further capital.

The difficulty in raising the tariff has been greater than the Board anticipated. The Manager in Chili writes thus: "The revenue has been affected by the general depression of business and poverty of the people. As it is impossible for any country to experience a long-continued and severe depreciation of its currency without each individual feeling more or less the evil effects, the inevitable consequence in the present case has been a general attempt to reduce expenses. It must be remembered that the greater number of the subscribers are Chilians, and with the exception of important business centres, such as Valparaiso and Iquique, the telephone is, more or less, a luxury; and to dispense with the annual charge which keeping it involves has appeared to be one of the first economies practised." The Board has, however, instructed the manager to make a further considerable addition to the tariff, at the risk of losing some subscribers; for it must be better to do a small but fairly profitable business than a large unprofitable one. As full notice of changes must always be given, it is not likely that much benefit will accrue from this before the beginning of 1895.

The Chairman, Colonel R. R. Jackson, retires, and the Board does not propose to fill the vacancy at present. The auditor, Mr. Thomas A. Welton, also retires, and offers himself for re-election.

An extract from the Manager's Report, dated Santiago, May 18th, accompanies the Directors' Report.

City and South London Railway Company.

The following is the report of the Directors of this Company to be submitted to the half-yearly ordinary general meeting, to be held at Winchester House, Old Broad-street, E.C., on Wednesday next, August 1st, at three o'clock:—

The receipts from all sources for the past half-year have amounted to £24,294. 17s. 6d., and the cost of working has been £14,990. 3s. 2d., leaving a profit of £9,304. 14s. 4d. Inclusive of the balance brought forward from December 31st last the net revenue account shows an aggregtae total of £10,368. 8s. 2d. After making provision for the debenture and debenture stock interest, a balance remains available for dividend of £6,295. 17s. 10d. Out of this sum your Directors recommend that the full dividend of 5 per cent. per annum be paid on the Preference shares, and that a dividend at the rate of 1 per cent. per annum be paid upon the Consolidated Ordinary stock, leaving a balance of £1,335. 17s. 10d. to be carried forward to the next account.

The following table shows the number of passengers, exclusive of season ticket holders, carried since the opening of the railway in each half-year:—

	No. of passengers (exclusive of season ticket holders).	Receipts (including season tickets).		
Ended Dec. 31, 1890 (11 days)...	165.000	£1,568	3	9
„ June 30, 1891	2,412,343	19,403	6	9
„ December 31, 1891	2,749,055	19,798	16	6
„ June 30, 1892	2,813.162	20,931	4	2
„ December 31, 1892	3,117.602	22,002	17	5
„ June 30, 1893	3,146,656	22,458	6	9
„ December 31, 1893	3,093,351	22,067	14	10
„ June 30, 1894	3,383,154	23,564	10	6
Total since opening of the line	20,830.323	£151,795	0	8

The Directors have great satisfaction in stating that the increased traffic has been carried punctually, and free from accident of any kind. The closing of the Oval for football militated against the traffic for the first three months of the half-year, but subsequently there has been a satisfactory increase. The actual cost of working the line for the past half-year has been somewhat less than for the corresponding period last year, but the Directors regret that the local rates again show a marked increase.

The locomotives, rolling stock, generating and other plant have been maintained in thorough working order and repair, as certified by the engineer. The alterations at the City Terminus are complete, and the additional accommodation thus obtained is a great convenience, especially on occasions when the traffic is heavy. The parcels office and left luggage room are in operation, and promise to be a remunerative source of revenue.

During the half-year £8,200 of the Terminable Mortgage Debenture Bonds have been paid off and reissued as Debenture stock, or Preference shares, at a premium.

The Directors have instructed the Company's engineer to make experiments with the view of substituting motors on the train itself in place of the present separate locomotive, with the object of adding an additional coach to each train. Should this change prove practicable the number of passengers capable of being carried will be considerably augmented.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1894, pages 274-300, *&c., &c.*]

BRITISH AND FOREIGN ELECTRIC AND ENGINEERING COMPANY (LIMITED).—This Company was registered on July 23rd with a capital of £2,000 in 50 Founders' and 1,950 Ordinary shares of £1 each, to carry on the business of manufacturers of and dealers in electric, telegraphic, surgical and scientific instruments, contractors for the sale, letting on hire, erection, and maintenance of and dealers in and suppliers of electrical engineering and other goods, and apparatus connected with the production of light, heat, power, or other force, electrical, mechanical, metallurgical and chemical engineers, electricians, electrical contractors, suppliers of electricity, merchants, &c., and also the general business of an electric light company in all or any of its branches. The subscribers (with one share each) are:—Harry E. Hopperton, Avando W. Hussey, Stanley W. Kelsey, Frederick Cottrell, William R. Reeve, Gordon R. Kelsey, and James A. Remon.

ELASTIC ENAMEL PAINT COMPANY (LIMITED).—This Company has been registered with a capital of £2,000 in £1 shares, to adopt an agreement, for the acquisition by the Company of certain letters patent relating to a new or improved composition or paint, to be used for coating and preserving metal, wood, and other substances and materials.

HARDWICK'S PURINE SYNDICATE (LIMITED).—This Company has been registered with a capital of £1,000 in £1 shares, to carry on business (*inter alia*) as chemical manufacturers, civil, mechanical, and electrical engineers, &c.

JOHN MILLS AND SONS (LIMITED).—This Company was registered on July 18th with a capital of £25,000 in 2,000 Ordinary, and 500 Five per Cent. Preference shares of £10 each, to carry on the business of brass founders and finishers, coppersmiths, tinsmiths, mechanical engineers, metal workers, machinists, metallurgists, electrical engineers, &c.

PATENT ENAMEL COMPANY (LIMITED).—This Company has been registered with a capital of £60,000, in 5,000 Preference shares of £7 and 10,000 Ordinary shares of £2. 10s. each, to acquire the business, goodwill, &c., of the Patent Enamel Company (Limited), incorporated 1883, and to carry on business as enamellers and enamelled plate and hollow-ware manufacturers.

WRAY ELECTRICAL ENGINEERING COMPANY (LIMITED).—This Company was registered on July 21st with a capital of £10,000 in £1 shares, to acquire the goodwill of the business of electrical engineers carried on at Bradford, under the style of the Wray Electrical Engineering Company, and to carry on the business of electrical and mechanical engineers, brass and other instrument makers, model makers, joiners, and dealers in electrical and mechanical goods. The subscribers (with one share each) are:—Cecil Wray, Joseph A. Jessop, Walter Ward, Harry Fox, William Wray, Richard Smith, and Frank Wall. Joseph A. Jessop and Cecil Wray are to be the Managing Directors for a period not exceeding two years.

FROGGATT'S ELECTRIC LIGHTING COMPANY (LIMITED).—The statutory return of this Company, made up to May 18th, was recently filed. The whole capital of £3,000 in 1,500 "A" and 1,500 "B" shares of £1 each has been taken up, of which the "B" shares were issued as fully paid to Thomas Froggatt. The full amount has been called and paid on the "A" shares, of which 1,493 are held by Messrs. Murrieta and Co., of 7, Adam's-court, Old Broad-street, London, E.C. A special resolution filed on May 29th had for its object the raising of the capital to £60,000, and the empowering of the Directors to purchase from Thomas Froggatt all the patents obtained by him up to the present time in and connected with electric lighting, together with the right to all improvements therein.

FROGGATT'S INVENTIONS SYNDICATE (LIMITED).—This Company is now defunct.

GREENWOOD AND BATLEY (LIMITED).—The annual return of this Company, made up to June 30th, has been filed. Out of a nominal capital of £400,000, divided into 14,000 Preference and 26,000 Ordinary shares of £10 each, 11,066 Preference and 18,052 Ordinary shares have been taken up, of which 2,666 Preference and 4,666 Ordinary shares have been issued as fully paid. Upon 6,934 Preference and 12,134 Ordinary shares the fully amounts have been called, while upon the remaining 1,466 Preference and 1,252 Ordinary shares calls amounting to £3 per share have been made, resulting in the payment of £198,834.

HOBART ELECTRIC TRAMWAY COMPANY (LIMITED).—The annual return of this Company, made up to December 31, 1893, has only recently been filed. Out of a nominal capital of £105,000, in £1 shares, 45,000 shares have been taken up, and 20,000 issued as fully paid. The full amounts have been called and paid on the remaining 25,000 shares. Share warrants to the total value of £1,250 are now outstanding.

INTERNATIONAL ELECTRIC SUBWAY COMPANY (LIMITED).—The annual return of this concern, made up to August 15, 1893, was not filed until the 9th inst. Out of a nominal capital of £25,000 in £1 shares, 21,857 have been taken up, and of these 20,000 have been issued as fully paid. Upon the 1,857 remaining shares the full amount has been called, resulting in the payment of £1,850, and leaving £7 in arrears.

IPSWICH ELECTRICITY SUPPLY COMPANY (LIMITED).—This Company has now ceased to exist, on account of the Board of Trade withdrawing the Order granted by them for the purpose of supplying the town of Ipswich with electricity, as the Company could not find the deposit of £800 required.

LONDON UNITED TRAMWAYS (LIMITED).—This Company has been registered with a capital of £50,000 in 2,500 Six per Cent. Cumulative Preference and 2,500 Ordinary shares of £10 each, to acquire the tramways undertaking and assets of the West Metropolitan Tramways Company; to purchase or construct tramways in the United Kingdom; to equip, maintain, and work with horse, steam, electric gas, or other mechanical power the tramways belonging to or leased by the Company, &c.

GEORGE MORITZ (LIMITED).—The annual return of this Company, made up to February 26th, has just been filed. Out of a nominal capital of £5,000 in £1 shares, 1,009 have been taken up, of which 1,000 (which are now vested in Mrs. Moritz), were issued to George Moritz, electrical engineer, in part consideration of the business of the Manchester and Liverpool Electrical Engineering Company, carried on by him. The full amount has been called and paid on the remaining 9 shares.

CITY NOTES.

CITY AND SOUTH LONDON RAILWAY.—The traffic returns of this Company for the week ended July 22nd were £839, as against £764 in the corresponding period of 1893, being an increase of £75. The total receipts for the half-year amount to £2,600, as against £2,609 for the corresponding period of 1893, a decrease of £9.

DISTRICT MESSENGER SERVICE.—Several alterations have been recently made in the management and direction of this Company, and applications have been invited this week for £25,000 Five per Cent. "A" First Charge Debentures, and £25,000 Six per Cent. "B" Second Charge Debentures. In addition to the services previously undertaken, the Company are now prepared to supply messengers for a variety of purposes, from delivering handbills to performing clerical work. The Directors anticipate from additional rent to be received from subscribers for call boxes, and from a material reduction promised by the Postmaster-General in the royalties, and from being in a position to more fully equip the present offices, and by the opening of new branches, to materially improve the position of the Company, and to render the service more effective.

EDINBURGH FINANCE.—The Corporation of Edinburgh have this week invited applications for £500,000 of Three per Cent. stock, redeemable at par on May 15, 1924. The issue of the stock is for the purposes of electric lighting, tramways, general improvements, &c. The lists closed on Wednesday, and applications will be opened this day (Friday), at 12 noon.

GULCHER (NEW) ELECTRIC LIGHT AND POWER COMPANY (LIMITED) (*in liquidation*).—An extraordinary general meeting of the members of the above Company is to be held at 73, Lombard-street, E.C., on Wednesday, August 1st, at 11 o'clock, for the purpose of considering and passing the following resolution:—"That Mr. Charles Fitch Kemp, the liquidator, be authorised to enter into an agreement with Easton, Anderson and Goolden (Limited), for the sale to that Company of this Company's plant, machinery and stock-in-trade at the price of £12,500, payable as to £5,700, part thereof, in cash, and as to £6,800, the balance thereof, in 680 shares of £10 each, fully paid up in Easton, Anderson and Goolden (Limited)." If the resolution is passed by the requisite majority it will be submitted to a second meeting, to be called later, for confirmation.

MANGANESE BRONZE AND BRASS COMPANY (LIMITED).—A final dividend of 8s. per share, making 14s. for the year to June 30th, has been declared by the Directors of this Company. £2,000 is placed to reserve, and £1,208 carried forward.

METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).—Letters of regret and allotment in the recent issue of £150,000 Four-and-a-Half per Cent. First Mortgage Debenture Stock in this Company have been posted.

SANITAS COMPANY.—A dividend at the rate of 10 per cent. per annum for the six months ended June 30th last, free of income tax, is declared by the directors of this Company, payable on and after the 1st September next. The transfer books will be closed from the 25th to the 31st August.

ST. JAMES' AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED). The share transfer books of this Company are closed up to Thursday evening next, preparatory to the payment of interim dividends on the Ordinary and Preference shares for the half-year ended June 30th last.

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee to appoint a special settling-day in, and to grant a quotation to, the Six per Cent. Cumulative Preference shares and Ordinary shares of Willans and Robinson (Limited).

WESTMINSTER ELECTRIC SUPPLY CORPORATION (LIMITED).—The Board have declared an interim dividend at the rate of 4 per cent. per annum for the half-year ending 30th June last, payable on the 1st September next.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended July 20th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £2,238.

THE SILVER JUBILEE

OF

SUBMARINE TELEGRAPHY TO THE FAR EAST.

CELEBRATED AT

The Imperial Institute, South Kensington, London, S.W.,

On FRIDAY EVENING, JULY 20th, 1894.

THE BANQUET UNDER THE PRESIDENCY OF

SIR JOHN PENDER, G.C.M.G., M.P.,

Chairman of the Eastern and the Eastern Extension Telegraph Companies.

THE EVENING FÊTE AND RECEPTION UNDER THE DISTINGUISHED PATRONAGE OF

HIS ROYAL HIGHNESS THE PRINCE OF WALES, K.G.,

And other Members of the Royal Family.

The twenty-fifth anniversary of the establishment of submarine telegraphy with the Far East was celebrated at the Imperial Institute on Friday last. The fête commemorating this important event, together with the various incidents of the anniversary, occupied nearly eight hours. The occasion was regarded as historic, and to do fitting honour to it, and therefore to an invention which, as the United States Ambassador observed in the course of the banquet, "has wholly changed the relations of mankind to each other," a brilliant and distinguished company assembled, including his Royal Highness the Prince of Wales, Field-Marshal his Royal Highness the Duke of Cambridge, her Royal Highness the Princess Louise (Marchioness of Lorne), Prince Edward and Prince Hermann of Saxe-Weimar, the Turkish, Italian, and United States Ambassadors, and many other members of the diplomatic body were present, together with men whose names are known throughout the world in Science, Politics, and Commerce.

At the banquet the Company numbered nearly 500, while the reception was attended by about 5,000 guests; and a party of about 60, including the Royal visitors, was entertained in the Fellows' dining-room, used on this occasion as the Royal supper-room.

The series of events opened shortly before 7 o'clock, when Sir John Pender, G.C.M.G., M.P., the Chairman of the Eastern and Eastern Extension Companies; the Marquis of Tweeddale, Mr. J. Denison Pender, and other members of the Boards of the two Companies, proceeded to the vestibule of the main building to welcome the banquet guests. The vestibule presented a splendid appearance, with its wealth of floral and other decorations. After their reception, the guests passed up the steps to the Great Hall porch, in the centre of which the Queen's statue stands, which had also been very tastefully adorned with flowers.

A few minutes after seven o'clock, in accordance with the programme, the Chairman and his co-directors, their first pleasant task accomplished, entered the banquet hall; and on taking their seats "the King of Cables"—as Sir John Pender was felicitously termed in a congratulatory telegram from the Director of Telegraphs at Rome—and his colleagues received a most cordial greeting, the Meister Orchestra, which was stationed in the gallery, welcoming the party with music. The dining-hall itself presented a magnificent appearance, and the temporary character of the structure was neatly concealed by its decorations and general surroundings. The chamber was brilliantly illuminated with the electric light, the supports of the hall were adorned with sheaves of flags of all nations, from the roof hung banners of the various colonies and dependencies of our mighty Empire, and the tables were tastefully "dressed" with choice flowers and lighted by tall wax candles prettily and effectively shaded, which served the double purpose of illumination and ornamentation.

During dinner the usual loyal toasts were given, and

The CHAIRMAN, whose rising was the signal for loud cheering, said: Gentlemen,—The first toast I have to propose is that of "Her Majesty the Queen." When the history of her reign is written it will be one of the brightest and most remarkable in English history—if not in the history of the world. Long may she live to reign over a united Empire, and a loyal and devoted people! (loud cheers.)

The toast was drank with enthusiasm.

The CHAIRMAN: The next toast I have to propose is "The Prince and Princess of Wales and the other members of the Royal Family" (cheers). His House has lately been strengthened and his home brightened by the birth of a Prince, let us hope the future King of England, and this no doubt will cheer him on in the arduous duty which he has to perform, and which he performs so well. His Royal Highness will honour us this evening by his presence, and in honouring us he shows his high appreciation of the great work which we are here this evening to celebrate (cheers). The other members of the Royal Family, following his example, are ever ready and willing to take part in any demonstration which is associated with the progress and best interests of the Empire.

After the banquet—

Lord KELVIN, in proposing the next toast, said: Sir John Pender, my Lords and Gentlemen,—In response to the Chairman's orders, I have the honour now to propose a toast unprecedented in the history of our country, "Armed Science, embracing the Army, Navy, and Auxiliary Forces." We know that every boy on the "Britannia" training-ship goes through a severe course of scientific instruction. He learns mathematics, astronomy, magnetism, electricity, chemistry, electrical engineering, and mechanical engineering. Every young lieutenant in the Navy knows more about astronomy, engineering—practical and applied—mathematics in all its branches, physics, and, I may say, science generally, than a senior wrangler of fifty years ago. Officers of Her Majesty's land forces—cavalry and infantry regiments—and the volunteer forces now possess opportunities of learning everything that is to be known in connection with scientific warfare. I have the honour of associating with this toast the name of an Irish soldier—a distinguished Irish soldier of the United Kingdom of Great Britain and Ireland. In the Crimea, West Africa, Egypt, India and Canada he has commanded Her Majesty's forces; in fact, he has served in all quarters of the world. I have the honour to associate this toast with the name of Lord Wolseley (loud cheers).

Field-Marshal VISCOUNT WOLSELEY: Sir John Pender, your Excellencies, my Lords, and Gentlemen,—I have to thank the noble proposer of this toast most cordially for the manner in which he has spoken of

Digitized by Google

Her Majesty's soldiers and sailors, and I wish him also to accept from me my deepest feelings of gratitude for the kind manner in which he has referred to me personally. It is no easy toast to discuss, especially in an after-dinner speech, and in the presence of the noble proposer. It is, in fact, one of the greatest subjects ever proposed in an after-dinner speech, and called upon now to respond to the toast in the presence of one whom I may call the great master of science in England — the noble lord who proposed this toast — I feel great diffidence in attempting to perform the task. I have not myself any experience of the appliances that refer to submarine telegraphy and the various arts and sciences in which the noble lord has made his mark; but still I have seen enough, both at home and abroad, to be able to appreciate the great advantages which the army and navy have derived from the establishment of these great lines of telegraphs all over the world (cheers). Submarine telegraphy, like all other great sciences, bears directly on the art of war quite as much as on the art of peace. I have often thought of the great differences that exist in the art of war now compared with the days of the great Duke of Wellington. Think of the immense difficulties under which he carried on his great campaigns, which would have been so much facilitated had there existed the present means of rapid communication by railways and steamships. I have often, in reading of those campaigns, tried to calculate to myself what would have been the result of many of the great Napoleonic campaigns had the present scientific means of locomotion existed in those days. Think, for example, what would have been the result of his great campaign in Russia if he had been in communication with Paris by railways and the telegraph. War is one of those great scourges of the world which I am afraid we can never get free from. Wars have always existed, and always, I am afraid, will do so, for war has always been regarded as the great final Court of Appeal by the nations of the world. I hope that a long time may pass before we have to take part in any great European war; but I hope also that if we should have to do so we may, as in previous wars, be benefited by the great men of science who will then have to be consulted. Perhaps it is not generally known that we were the first people who made use of telegraphy in war—in the Crimea. We also laid down a line of submarine telegraph between Varna and the Crimea, and I believe that that was the first time that submarine telegraphs were made use of for the purposes of war. I repeat that I hope war may be a long way off, but if ever the time does come when we have to be engaged again, I hope we shall be prepared for it by getting ready in time of peace (cheers). Judging from what has taken place in recent years, there is a disposition now to secure that object, whatever Government be in power (hear, hear). Let us hope also that the moral training of our men, both soldiers and sailors, may keep pace with their scientific knowledge, and that they may remember in moments of victory to extend that sympathy for human suffering which, after all, has been in all times the noblest distinction and the greatest merit of truly brave men (cheers).

Then followed the toast of the evening, "Submarine Telegraphy: In its International and Commercial Aspects." This toast was proposed in two parts, the United States Ambassador treating of the subject from the view of its international importance, and the Right Hon. the Lord Mayor of London (Sir G. R. Tyler, Bart.), treating the subject from its commercial aspect.

The United States Ambassador (the Hon. T. F. BAYARD) said: Sir John Pender, your Excellencies, my Lords and Gentlemen, I am asked to deal with the international aspect of submarine telegraphy. There is said to be no royal road to the learning of science, and that it must be approached by rugged ways; and yet it would seem that in the temples of science and of learning there are chambers of delight and pathways of pleasure by which we may learn to contemplate the results which have been reached by the most vigorous exercise of the human faculties (hear, hear). Here in this beautiful hall, amid the munificent hospitality of Sir John Pender (cheers), we are conducted in luxury and comfort to a contemplation of that which was not won by ease or by comfort, but which was only arrived at through long study, through painful endeavour, through great sagacity, through courageous enterprise, through that pluck (for no other word than that English word fulfils its meaning) which stood by a conviction until the fruits of triumph were attained (cheers). And here, in this hour of his truimph and success, when, accompanied by years that have brought him honour and fortune, and the gratulations of his people and of all peoples (cheers), I cannot be unmindful of one of my own countrymen, whom I cannot but wish could have shared the feelings generated by such an assembly as this, when "the silver wedding," pleasantly so called, between the great East and the Isles of Great Britain come to be celebrated (cheers). I could wish it were possible that Mr. Cyrus W. Field could but hear the voice of his great associate and brother in this wonderful enterprise—the wonderful enterprise of which this great feast is but a very small feature. "After life's fitful fever he sleeps well." I am glad to speak his name in this assembly, and "his countryman doth call as just witness" the English brother who took his hand in the hour of dire extremity of a great experiment (cheers). But how shall we consider the subject of submarine telegraphy in a worthy way? It will not do to pass it off with jocularity; it will not do merely to shake hands over it; and it certainly will not do, on an occasion like this, when we all feel so happy and so pleasant, to make it too serious. But it is all so marvellous. I feel, in standing in front of such an idea, and an idea that has found such a marvellous practical illustration, that commonplaces will not do. Small thoughts all vanish, and yet with all there is, happily for the relief of poor human nature, what the English judges used to call "a condescension to humanity." There is a humorous side which you cannot possibly banish, and I do not know that you will blame me if I bring it in. We were wont to consign, as a final place, everything that was lost to "Davy Jones's locker," and yet it seems to me that of all the secure places on earth for the secrets of Governments, for the messages of the lover to his mistress, for exery conceivable transmission of human feeling or human thought, "Davy Jones's locker" has become the safest (cheers). Sometimes—but you know it is an injustice—Americans have been accused of certain extravagances of speech (laughter). I heard of one orator, whom we place—or locate, to use an American word —in the Western States, boasting of someone who was running for Congress, that he could dive deeper, stay under longer, and come up drier than any man in creation (laughter). Now, I think that even my friend from the Western States who made that speech would be obliged to confess that he was not at all equal to one of Sir John Pender's submarine messengers, for he can dive deeper, stay under—I will not say longer, but he stays a sufficiently long time—and he certainly comes up dry enough, as dry as could be wished (laughter and cheers). There are a thousand other sides to this subject. Believe me that an invention permitted thus to break in upon the human mind, and which we in our conceit term a "discovery," an invention, or a perception, call it what you will, that has wholly changed the relations of mankind to each other—such an invention cannot be trammelled up in any speech. But it has changed men's relations to each other. War it has changed. No men living can feel this more than the distinguished soldiers who sit at this table within the sound of my voice. They know the blessed power of the submarine telegraph to make war unnecessary, if not impossible. If there is truth in what I say, if there is not exaggeration, what more need be said for submarine telegraphy? May I give you an instance? There was a war, and please God it shall be the last war, between England and the United States—(loud cheers)—eighty years ago. A most unnecessary battle was fought, and blood was shed that all must regret, for the want of a submarine telegraph. The battle of New Orleans was fought in 1815, on January 8th, and peace had been declared in the month of December previous at Ghent, and yet there was no means of communicating the fact. There was an unnecessary battle. A gallant, able general, and his equally gallant associates, fell uselessly before those piles of cotton bales in New Orleans, and they fell because, in the providence of God, the light had not yet dawned on the brain of man that peace could be proclaimed to the end of the world. And this piece had been agreed on, but there was no means of carrying the glad tidings across the Atlantic. That is but an instance. I mention it because it was the last conflict between men who speak the same mother tongue, and whose mother tongue was never so promoted and assisted as it is now by the free intercommunication of the submarine telegraph. My friends and brothers in the Diplomatic Corps are present, but they will understand that there are family ties which all respect; and I cannot but reflect that submarine telegraphy between Great Britain and the United States needs no translation (cheers). In the same tongue in which it is sent forth so it is received, and let us who are to use that language see that it shall convey nothing that cannot clearly be understood. It is the misunderstanding, the ignorance of men of each other's motives and objects, that is the parent of suspicion and the parent of doubts, which the clear, open word of free intelligence would dissipate for ever. It cannot be otherwise when men fairly understand each other, with opportunities of meeting, with time and space annihilated, and with an element which used to be pictured by the orator and the poet as a source of danger—the turbulent ocean—serving to-day as the connecting link of peace and quiet between nations (cheers). The truth is that the subject is so vast, the results of this discovery are so far-reaching, that one cannot on such an occasion do more than touch the fringe of it. It is a subject that should sink very deeply into our minds and our hearts, and I have been made to feel it practically, for I have been a working man in the affairs of Governments since I came to manhood. The great thing would be that we should lift ourselves, or seek to be elevated, to the level of the great thought, of the great duty, of the great capacity that this discovery has permitted us. Nothing is more wonderful in the world's history than this wonderful glimpse of science. I feel that a man must go back to the Book of Job, with all its sublimity, if he desires to find fitting language in which to clothe his thoughts when the possibilities of the submarine telegraph are open to him. One idea, one feeling should pervade us. All the world over—in Egypt, the Netherlands, France, Russia, the Great Orient—go where you will (and, of course, you will go to America), there should be but one feeling: that as this great mystery of intercommunication, so instantly and fully, is open to us, we should strive to prove that we comprehend it, are worthy of it, and intend to make its agency something more for the infinite advancement of our race (loud cheers).

The Right Hon. the LORD MAYOR of London then said: Mr. Chairman, your Excellencies, my Lords, and Gentlemen,—In proposing the important toast with which I have been entrusted this evening, namely, "Submarine Telegraphy, in its Commercial Aspect," very few words of mine are needed to recommend it to your consideration. The progress of submarine telegraphy during the twenty-five years since it was extended to India and the Fast East has been remarkable, and its effect upon commerce throughout the world cannot be over-estimated. It has practically revolutionised mercantile methods, by enabling merchants to exchange views and carry through business transactions in a few hours, or even minutes, where formerly many weeks or months were occupied. Thus the area of trade has been greatly enlarged, and many comparatively small merchants have been enabled to successfully engage in business who, under the old conditions, would have found it quite impossible to live. In fact, submarine telegraphy has now become such an important factor in commercial, social, and political life that it is no exaggeration to say that it is indispensable to civilisation (cheers). This great work has been built up quietly and unostentatiously by private enterprise, and mainly by British capital, and

Digitized by Google

when its history comes to be written, it will probably be described as one of the greatest achievements of the Victorian or any other age. Fortunately, submarine telegraphy has had associated with it distinguished men both in science and commerce, to whom the world is much indebted for the valuable facilities which they have been instrumental in providing. Twenty-five years ago submarine cable companies were looked upon with considerable mistrust by the investing public, but now, owing to the improved appliances and experience gained in laying and maintaining cables, their stocks are recognised to be first-class securities, and are, in fact, particularly free from those fluctuations in market prices that are so common to many other classes of securities. I couple with this toast the name of your Chairman, Sir John Pender. (Loud cheers).

The toast was drunk with great enthusiasm, and Sir John Pender, on rising to respond, was received with round after round of applause. When this applause had subsided,

Sir JOHN PENDER, G.C.M.G., M.P. (the Chairman), in reply, said:—Your Excellencies, my Lords, and Gentlemen: The eloquent remarks which have been made by the United States Ambassador and by the Lord Mayor of London in regard to submarine telegraphy make it a duty and a pleasure for me to refer in a few words to those early days when submarine telegraphy had its troubles, its disasters, and its triumphs. The United States was conspicuous in the part it took, not only in its scientific but also in its commercial aspect, and the names of Morse and Cyrus Field will ever be associated with it. I was connected with it at its dawn, and am still connected with it in its successful and permanent establishment. (Cheers.) When it was almost impossible to raise money for the 1865 cables, the Telegraph Construction and Maintenance Company was formed, over which I presided, and we are indebted to that Company for the good work they then and have ever since done. Even in those early days, when the 1865 cable had parted in mid-ocean, it was proved by our late colleague and Managing Director, Sir James Anderson, to be possible to pick up and repair a cable in 2,000 fathoms of water, and this important fact largely increased public confidence in submarine cables as a property. For this great work I feel that all credit is due to Sir James Anderson, who devoted the best years of his life to the development of submarine telegraphy; and, had he done nothing else, this of itself must always rank as a very great and important work in aiding and assisting the progress of submarine telegraphy throughout the world. We are also indebted to Sir William Thomson (Lord Kelvin), Cromwell Varley, Fleeming Jenkin, and many other distinguished men whose names will readily occur to you, for their scientific inventions, which enabled submarine telegraphy to achieve the great scientific and commercial success it has since become (cheers).

At the present time there are eleven cables in the Atlantic, and another is in course of submersion, so that with the aid of "duplex working," for which we are indebted to Dr. Muirhead and others, the carrying capacity is practically equal to twice that number. The first attempt to provide the public with submarine telegraphs to the East was in 1859, when a cable was laid down the Red Sea and along the coast of Arabia and through the Persian Gulf to Kurrachee. Unfortunately, this cable only worked a few days in its entire length, and was afterwards abandoned. The success attending the Atlantic cable caused the idea of submarine telegraphic communication to the Far East to be again considered, and it was carried into effect by the formation of various companies, which were afterwards merged into the Eastern and Eastern Extension Telegraph Companies, whose twenty-fifth anniversary we are now celebrating (loud cheers).

Twenty-five years ago yesterday the Company that laid the submarine system from Great Britain to the Far East was registered. At that time the nucleus of the present system of Eastern Telegraphs consisted of about 900 miles of cable, with a capital of £260,000. To-day we own 51,325 miles of cable, and have a joint nominal capital of over nine millions sterling, but which, at the present market quotations, actually represents nearly fifteen milllions sterling. Two years after the registration of the Eastern Companies, the whole submarine system between Great Britain and China was completed and in working order. A year later the Australian Colonies enjoyed the benefits of daily intercourse with the mother-country and the rest of the world.

It is worthy of note that none of these companies were, in their early days, assisted by any Government monopolies, subsidies, or guarantees, as in the case of the original Red Sea cables, so that it may be truly said that the Governments and mercantile communities of the world owe the benefits arising from direct submarine communication during the past twenty-five years entirely to British enterprise, and I am glad to be able to welcome here this evening some of the original shareholders, who took such a practical interest in our initial difficulties and risks. In those days submarine telegraphy was looked upon as a very risky investment. To-day it is recognised as one of the soundest investments in the market, and during the last two or three years of financial crisis this fact has been repeatedly demonstrated (hear, hear).

This great system of submarine telegraphs having once been launched upon its career, it was impossible for it to remain stationary, and the watchword of its Directors has ever been "Onward!" so that its benefits have been extended to all parts of the Eastern hemisphere by companies arising from the Eastern Telegraphs, and which are to a very large extent under their management. South Africa was also connected by companies associated with the Eastern Telegraphs, and quite recently communication with Chili and Peru has been further strengthened by the establishment of additional lines, under my own presidency, across the Andes, thus bringing us into direct working with the allied company that owns cables between Valparaiso and Lima (cheers).

In short, wherever the British flag flies, and commerce warrants a fair prospect of remuneration, cables have been laid, and this policy will be continued in the future. Within the last twelve months the Seychelles, Mauritius, Labuan, and Borneo have been added to our system. The Islands of the Azores have been connected with Lisbon, and, consequently, with London, and this connection will eventually be extended to America.

At present the total mileage of submarine cables is, in round numbers, 152,000 miles, of which 90 per cent. has been provided by private enterprise, and 10 per cent. by the various Governments, costing altogether over 40 millions sterling. The total length of land wires throughout the world is over two million miles, estimated to have cost about 65 millions. If the cables and land lines are added together a combined capital is represented of 106 millions sterling. The total imports of the world amount to nearly 1,940 millions sterling, whilst the total exports amount to 1,720 millions; and as commercial operations are now begun and ended by means of the telegraph, it will be seen that these vast figures have an important bearing on submarine telegraphy.

The greatest care and caution has had to be observed in the management of these companies. In the first place, the life of a cable was, and still is, to a large extent, an unknown factor. In the second place, to enable it to obtain a strong hold upon commercial life, it was necessary that submarine telegraphy should be always available, and this was only possible by having the system duplicated, and in some places triplicated and quadrupled. This has been carried out very thoroughly, the Eastern Telegraphs having expended since their establishment nearly five millions of money in strengthening their lines, and this policy has met with its reward by gaining for the Companies the increased confidence and support of the political, social, and mercantile communities. Governments have also shown their high appreciation of submarine telegraphy. Indeed, one of our leading statesmen, recently remarking on its great progress and vast sphere of usefulness, said that he looked upon it as one of the greatest achievements of the Victorian age, if not in the history of the world (loud cheers).

As you are aware, an important conference has recently been held at Ottawa, at which representatives of Great Britain and our Colonies met to discuss trade and other matters; but the main question before them was that of connecting the Australasian Colonies with Canada by a submarine cable across the Pacific. At the present moment Canada and Australia can communicate with each other through the existing system in a couple of hours or less, and at a comparatively moderate cost; but when a Pacific cable is really required, the Companies which I represent will not be backward in meeting public requirements; and as we have large experience and facilities for carrying out and maintaining such a work we ought to be able to undertake it on more favourable terms than any outsider could possibly do (hear, hear).

The Australasian Colonies during the last 25 years have shown their appreciation of the benefits of submarine telegraphy by assisting the Eastern Extension Company with a substantial subsidy to duplicate its cables between Penang and Australia. The majority of the Australasian Colonies also entered into an arrangement with the Eastern Extension Company, under a guarantee of half risk, to reduce the rates by 60 per cent., so confident were they that cheap tariffs would largely increase the traffic; and, although a considerable increase resulted, it was not nearly sufficient to recoup the loss; still, the increase had been such as to justify the experiment, and I have no doubt that, when prosperity returns to the Colonies, we shall see a very great development in the traffic, so that in time the loss will be entirely wiped out. I may mention that during the great commercial crisis that recently passed over the Australasian Colonies, and, in fact, all over the commercial world, submarine communication with Australia was found to be of enormous value in connection with the banks' reconstruction schemes found to be necessary, thus greatly assisting in restoring confidence to the commercial community, and in allaying the uneasiness which might otherwise have resulted in panic (cheers.)

Twenty-five years ago it was considered wonderful to receive a message from India in a few hours; to-day, telegrams arrive in a few minutes. We commenced business by carrying at the rate of 400,000 messages per annum; to-day we transmit over two millions. Our communications are maintained by nine steamships, fully manned and equipped with all the latest scientific appliances for at once repairing the cables when broken, and it may be mentioned that up to the present time the Eastern Telegraphs have never been unsuccessful in the restoration of any of their cables (cheers.)

A *résumé* of the history of submarine telegraphy to the Far East would not be complete without mentioning that few events of international interest take place in which submarine telegraphy has not played an important part. An event which exemplified more than anything else the capabilities of the telegraph, and proved to the world its enormous value, was the bombardment of Alexandria, and the subsequent operations in Egypt, the Soudan, and at Suakin. It is not too much to say that during this time the public were kept in hourly touch with all the events, even to the minutest detail, that were happening in Egypt, and the Eastern Company is justly proud that the immense traffic which they then carried was brought through without practically any delay at all (loud cheers).

In conclusion, it may safely be said that submarine telegraphy has been provided wherever required by commerce, and that it has been enormously beneficial to the public at large, by bringing them into closer knowledge of the every-day life of their kindred beyond the seas, and assisting in keeping together the great fraternity of the Anglo-Saxon race. It has undoubtedly equalised trade throughout the world, and brought the producer and consumer closer together, enabling the producer to obtain a better market, and the consumer the benefits of international competition. It has over and over again prevented diplomatic ruptures and consequent war, and has thus been instrumental in promoting peace and happiness throughout the world.

I cannot finish without acknowledging the good work and hearty cooperation which we have received from our Danish friends, the Great Northern Telegraph Company, who share the China and Japan traffic with

Digitized by Google

us, and with whose officials, from their able Chairman and Managing Director (Mr. Tietgen and Commodore Suenson) downwards, we are on the best of terms. I also desire to publicly acknowledge the good work and co-operation which we have always received from our officers and staff throughout the service, many of whom are present with us to-night. Without their help it would have been impossible to attain such satisfactory results as we have been able to achieve during the last twenty-five years (loud cheers).

The LORD CHANCELLOR (the Lord Herschell): My speech must be, happily for you, and still more happily for me, very short. I have to propose "Our Colonial and Indian Empire." We all feel proud of belonging to an Empire that can boast of such colonies and dependencies; and I am quite sure that while we feel that pride, our hearts go forth to every part of our distant Empire. We rejoice when they rejoice, we sorrow when they sorrow. Until recent years we only heard of either their troubles or their sorrows weeks or months after they had occurred. We could not at that time rejoice or sorrow with them. The great system of submarine telegraphy has changed all that (cheers). We now hear of the events that move their hearts as soon as they have occurred, and our hearts move with theirs, and our sympathies are immediately with them (cheers).

The Right Hon. H. H. FOWLER, M.P. (Secretary of State for India), first responded to the toast. He said: Sir John Pender, my Lords, and Gentlemen,—I feel it a very great honour this evening to respond on the part of our Indian Empire for this toast, and to acknowledge, in the name of that Empire, the great obligations under which it is laid, both in its administration, commerce, and defence, to that institution which you are assembled to-night to celebrate on the occasion of its twenty-fifth anniversary. I quite agree that all the speeches on this occasion must be confined to short limits, and I will only say, in one sentence, that I believe that the rule of Great Britain has been an unspeakable boon to the people of India; that that rule is alike just, impartial, and effective; that it guarantees the liberties, secures the peace, develops the resources, and promotes the prosperity of the Queen's subjects in that great Empire. I acknowledge in their name and on their behalf the debt they feel towards this institution, which connects them, I may say, day by day and hour by hour, in all the details of their daily life and of their Imperial interests, with the centre of the Empire—with the Home Government (cheers.)

Sir CHARLES TUPPER, Bart. (High Commissioner for the Dominion of Canada), also responded. He said: I have great pleasure in returning thanks for the very kind and appreciative manner in which the Lord Chancellor has referred to the Colonies. I need not, I am happy to say, detain you much with reference to the history of telegraphy or to the wonderful results of that great discovery. You have listened to the graphic description of telegraphy which has been given by our distinguished chairman, Sir John Pender, and to the eloquent words that are still ringing in your ears regarding the results of the discovery upon the nations of the world which were addressed to you by the representative of the United States of America, whom I am proud to see present among us to-night (cheers). I need not say that, great as has been the progress of the Colonies during the past fifty years, that progress during the past quarter of a century has been greatly emphasised, greatly increased, by the efforts of those great Companies whose services to their country we have met here to-night to celebrate, and I have no hesitation in saying that a great deal of the success, a great deal of the advancement of the Colonies has been due to the energy and ability of the distinguished gentleman who is now presiding over us (loud cheers). I need not go further than to say that you can appreciate what submarine telegraphy means to the great continent of Australia by mentioning a fact of which I am just reminded by a colleague—that the exchange of messages of the most vital importance, which took months to effect a few years ago, can now be accomplished in a few hours by this great discovery of submarine telegraphy (cheers). I will not at this late hour venture to interpose between this gallant company and the ladies, who will be waiting to receive you at the other end of the building, but will conclude by again thanking the Lord Chancellor for the kindness with which he has referred to the Colonies, and this great and distinguished company for the gracious way in which they received the toast (cheers).

The MARQUIS of TWEEDDALE (Vice-Chairman of the Eastern Telegraph Company) proposed the next toast, "Our Guests." He said: Sir John Pender, your Excellencies, my Lords, and Gentlemen,—The toast entrusted to my hands is fortunately one which needs only to be mentioned to ensure a cordial reception. It is that of the health of those who have honoured us this evening with their company as our guests, and when I look around and see the representatives of many nations, of our great colonial Empire, of our cousins across the sea, of our Indian Empire, of our industrial and scientific institutions, and last, but not least, of the great Press of this country, I cannot but feel proud—and I believe that that pride is shared by Sir John Pender—at the reception you have given to our hospitality this evening. I infer from the manner in which you have received Sir John Pender and ourselves that you wish to show your approval of the manner in which we commenced this great enterprise twenty-five years ago, and which it has taken a quarter of a century to bring to the perfection in which it now is (cheers). I am especially proud to think that so many nations of Europe are represented to-night, because I feel that that affords the best evidence of the purely international manner in which we have conducted this great enterprise; and I am glad to be able to make an announcement to-night which I am sure will be received with pleasure by all Sir John Pender's admirers. It is in the form of a communication from His Majesty the King of Italy, who states that upon the proposal of the Minister of Posts and Telegraphs he has been pleased to confer upon our Chairman the distinction of the Grand Cordon with the Grand Cross of the Order of the Crown of Italy (cheers). This, gentlemen, is only one of the numerous honours which have been bestowed upon our Chairman by the other nations of Europe. I had intended to occupy your time at some greater length, but at this late period of the evening it would not be proper to do so, and I will therefore merely conclude by associating with this toast the name of a distinguished member of the bench of this country, one whose learning is only equalled by his wisdom and his wit. I refer to Lord Morris. I beg leave now to propose "Our Guests," and to couple it with the name of our distinguished guest, Lord Morris (cheers).

Lord MORRIS: Sir John Pender, your Excellencies, my Lords, and Gentlemen,—It certainly did surprise me that one in my humble position should be asked to return thanks in this cosmopolitan assembly for the guests of the evening. I perceive about me great ecclesiastics, great soldiers, great men of science, and great men of every position; and I again ask myself why Sir John Pender has imposed this duty upon me. I can only discover one answer—that he is anxious that one should address you who always boasts of being—and if he chose to deny it his voice would at once betray him—a representative Irishman (laughter). I am proud of the kindness which has been shown to me, and as a member of this United Kingdom—which I always hope to remain a United Kingdom—to return thanks for this great assembly of guests, who represent all parts of the world. Why an Irishman should be selected to speak on their behalf is, pealiaps, a little strange (laughter). We have it on the highest authority that the wise men came from the East: but I come from the West. I look upon it with great satisfaction that the duty has devolved on me of returning thanks for the toast of the guests, and having discharged that task—very inadequately, as I feel—I have now to address you again, and to call upon you to fill your glasses and discharge your duty as guests by drinking the health of Sir John Pender (loud cheers). It is 29 years ago since I first remember being acquainted with Sir John Pender as a member of the House of Commons. I have watched his career since with interest, as many men in this company must have watched it. He is a man who, having first devoted himself to commercial pursuits, acquired a fortune which enabled him to attend to the interests of his country in the direction of this great and important industry. He was then one of the first men, if not the first, to take a leading position in the establishment of submarine telegraphy (cheers). Several of us are old enough to remember the repeated failures with which the attempt to lay a cable between the Western Continent of America and this country was met. We remember when the "Great Eastern," carrying the cable, after repeated failures, finally lost it in mid-ocean, and nearly everyone abandoned all hope about it. There was, however, one man who abated not one jot of faith, but who assisted not alone by his personal endeavours and as a member of a Corporation, but who, if my memory serves me aright, personally offered his own security for a quarter of a million of money in order to establish a new submarine telegraph (cheers). That is a circumstance which does not often occur in practical life. But he succeeded, and I have no doubt that he has enjoyed the benefit of his success, commercially and in other senses. Having connected the continent of America with this country, his efforts did not cease. He endeavoured, and successfully, to carry out a system of submarine telegraphy to our Eastern countries, and in this manner millions have been expended. It was said by some at the outset, "Why, you might as well throw money into the sea." Well, millions have been "thrown into the sea," and with very great benefit to all who have enjoyed the blessings of this great invention (cheers). Our friend Sir John Pender is, in one word, the greatest unionist of the age, for he has not alone united these small islands, but also the whole world in one encircling girdle (cheers). Without further preface at this late hour of the evening, although I could go on for a long time on the subject of Sir John Pender and his career, I will conclude, as I am sure that he himself would be better pleased that I should wind up. I ask you, however, in conclusion, to drink the health of our Chairman with all the honours—the health of a man who has shown himself the dominant spirit of submarine telegraphy and the dispenser of generous hospitality (loud cheers).

The toast was drunk with the greatest enthusiasm.

The CHAIRMAN: My Lords and Gentlemen,—There are periods in a man's life when he opens his eyes, looks round, and wonders at his surroundings (laughter). To-night I am really astonished at the extraordinary response that has been made to our appeal to come and meet us to-night at the celebration of our 25th year. When, however, I say that, I must tell you that there is not a morning in my life that I do not wonder at the extraordinary success which has attended submarine telegraphy, and at the extraordinary power it possesses, and at the extraordinarily efficient way in which it has been conducted by these companies. The success of these companies, no doubt, has been owing to the united way in which they have been conducted. I have had the most hearty support, for which I thank my colleagues, and we have been enabled to give to the world what I believe to be one of the greatest, and probably the greatest, achievement in the Victorian reign, and also, as a very distinguished statesmen said to me the other day, probably the greatest achievement in the world's history (cheers). I am very much indebted to you for the compliment you have paid to us this evening, and on behalf of my colleagues and myself I tender you our sincere thanks. As I have said before, while our work has been great and prosperous in the past, we have still much work to do in the future, and I believe that that work will be as successful in the future as it has been in the past if the same energy, the same judgment, and the same industry are applied to it. I thank you very much for your presence and your support. You have not only given us support, but also encouragement to look forward to the future, and, if possible, to excel what we have done in the past (loud cheers).

The following is a list of the guests at the Banquet :—

And the representatives of all the leading London, provincial, and Colonial journals, and of the Telegraphic News and Press Agencies.

It was shortly before 10 o'clock when the banquet guests separated, and many of them at once proceeded to the gardens, which were brilliantly illuminated, and in which the bands of the Grenadier Guards and the 1st Life Guards played.

Sir John Pender, with his co-Directors, returned to the Vestibule, where they were joined by the Marchioness of Tweeddale, Mrs. J. Denison Pender, Mrs. Bevan, Mrs. James Pender and others, when the second great function of welcoming the guests to the reception immediately began, and occupied nearly two hours, the Meister Orchestra playing during the ceremony. Between 9,000 and 10,000 invitations had been issued, and about 5,000 guests were happily able to be present. The names of those who accepted the invitations are given below. Where gentlemen represented the institutions with which they are associated, the name of the Institution is given:

Agra Bank
Aldridge, Salmon and Co.
T. H. Allan and Co.

And the Representatives of the London, Provincial, and Colonial Journals, and the Telegraphic News Agencies.

Immediately after the reception, having been provided with programmes, the guests proceeded to the grounds and the galleries, other than the upper central gallery, where the exhibition of telegraphic apparatus was placed, the first inspection of which, as the guests had been notified, was reserved for the Royal visitors. The grounds were delightfully cool, and presented a charming appearance with their brilliant illuminations. The weather continued fair till towards quite the end of the proceedings. The band of the Grenadier Guards, conducted by Lieutenant Dan Godfrey, was stationed in the West Garden, and the band of the 1st Life Guards, conducted by Mr. Joel Englefield, played in the East Garden. Refreshments were served at various places in the grounds, and also at a buffet in the North Gallery, where there was a fine display of British china, glass, and pottery. Subsequent to the Royal visit the exhibition of telegraph apparatus was open to the company generally, and, under the able guidance of several of the Eastern Company's officials, the guests were initiated into the essential features of submarine telegraphic work.

On their arrival at the main entrance shortly after half-past eleven o'clock, the Prince of Wales and the other Royal guests were received by the Lord Chancellor, chairman of the governing body; Sir Frederick A. Abel, Bart, K.C.B., secretary and director of the Imperial Institute; and Sir Somers Vine, C.M.G., assistant secretary and general sub-director of the Imperial Institute, and were conducted by them to the Vestibule curtain, where Sir John Pender and his

Digitized by Google

colleagues welcomed them. After their reception the Royal party and suite, escorted by the acting stewards, headed by Mr. Bean proceeded by the main Vestibule steps to the eastern foyer in the upper central gallery, and, with a few specially invited guests, inspected an exhibition of telegraphic apparatus, in which and in the explanations of Lord Kelvin and Sir John Pender the greatest interest was manifested. The exhibits comprised the following:—

Case containing specimens of the Types of Cable connecting England with Bombay, via Egypt.
Case containing specimens of various Cables laid for the Eastern Telegraph Company.
Case containing specimens of the Types of Cable used in the Eastern Telegraph Company's Trieste-Corfu Section, laid in 1882.
Case containing specimens of the Types of Cable in the Triplicate Red Sea Section, laid in 1883.
Case containing specimens of Cable laid in the Mediterranean in 1887.
Case containing specimens of the Eastern and South African Telegraph Company's Cables.
Specimen of the 1861 Malta-Tripoli-Bengazi-Alexandria Cable. Recovered off Tripoli thirty years after submersion.
Picked-up lengths of Red Sea Cable, covered with marine growth.
Pieces of the original Suez-Souakim Cable with Coral growth, recovered by the s.s. "Chiltern" in 1890.
Specimens of submarine vegetation picked up in the Straits of Malacca.
Growth removed from Cable picked up in the Red Sea.
Boring worms which attack Cables, causing faults.
Microscopic drawing of the head of a boring worm.
Various faults caused by Teredo borings, and a specimen of brass-taped Cable now adopted for prevention of same.
Snake found coiled round Cable during repairs off Batavia.
Adder picked up with Cable repairs off Saigon.
"Feather" star-fish taken off Cable during repair.
Deep Sea Fish.
Profile chart of the North Atlantic Ocean, showing the Cables.
The Grapnel used in recovering the 1865 Atlantic Cable.
Model showing how light-ships are connected by Electric Cables to the shore.
Mirror and recorder key taken from Alexandria Office after it had been broken into by the rebels during bombardment of town.
Four direct-working Morse instruments, complete.
Four Saunders' fine-wire tube lightning guards.
Four Bullock and Brown's unigraphs.
The original messages which passed between Lord Monck, John Pender, Esq., and the Directors of the British Australian Telegraph Company —and the Chairman of a banquet held at Adelaide to celebrate the completion of telegraphic communication between England and Australia, 1872.
And Maps showing the complete Cable system of the World; the African Cable system; the Eastern Extension and China Telegraph Company's system and the Cables on the West Coast of America; and the Eastern Telegraph Company's Map, shewing the complete Cable system of the World, with each Telegraph Company in a distinctive colour.
Model of the s.s. "Great Eastern."
Models of the Eastern Telegraph Company's Cable Ships, "John Pender," "Chiltern," "Mirror," "Electra," and "Amber."
Model of the Eastern Extension Telegraph Company's Cable Ship "Recorder."
Model of the Eastern and South African Telegraph Company's Cable Ship "Great Northern."
Sir William Thomson's (Lord Kelvin's) first complete syphon recorder for working long Cables. (1870.)
Latest form of Thomson's syphon recorder—(designed by Dr. Muirhead)—worked by automatic sender, through an Artificial Line electrically equal to 1,000 miles of Submarine Cable.
Symbolical Drawings, by Ambrose Dudley, representing Europe, America, Asia (including Australasia), and Africa, which were placed over the instruments working to those quarters of the world, were much admired. The Prince of Wales making particular enquiries as to the artist.

The Prince of Wales and his Royal relatives had completed their inspection of the exhibits by about half-past twelve o'clock, at which time they proceeded to the Royal supper room, outside which the Roumelian National Band played. The following is the full list of those for whom covers were laid:—

H.R.H. the Prince of Wales, K.G., H.R.H. the Duke of Cambridge, K.G., H.R.H. the Princess Louise (Marchioness of Lorne), H.S.H. Prince Edward of Saxe Weimar, H.S.H. Prince Hermann of Saxe Weimar, the Turkish Ambassador, the Italian Ambassador and Lady, the United States Ambassador and Lady, the Persian Minister, the Danish Minister and Lady, the Portuguese Minister and Lady, the Netherlands Minister and Lady, the Japanese Minister and Lady, the Servian Minister and Lady, H.H. the Maharajah of Kuch Behar, the Duke of Fife, K.T., the Marquis of Lorne, K.T., G.C.M.G., Sir John Pender, G.C.M.G., M.P., chairman, the Marquis of Tweeddale, vice-chairman, and Lady, the Lord Chancellor and Lady, the Chancellor of the Exchequer and Lady, the Right Hon. H. H. Fowler and Lady, the Marquis of Salisbury and Lady, the Marquis of Lansdowne and Lady, Viscount Cross and Lady, Field-Marshal Viscount Wolseley and Lady, Admiral Lord Hood and Lady, General Lord Roberts and Lady, Lord Kelvin and Lady, the Right Hon. Lord Playfair and Lady, the Right Hon. J. Chamberlain and Lady, the Lord Mayor and the Lady Mayoress, Sir Redvers Buller and Lady, Sir Frederick Abel, Sir Robert Herbert and Lady, Sir Somers Vine, Sir A. J. Leppoc Cappel and Lady, Mr. F. A. Bevan and Lady, Mr. James Pender and Lady, Mr. J. Denison Pender and Lady, Mr. G. Draper, Mr. F. E. Hesse, Mr. H. A. C. Saunders, Mr. W. T. Ansell, Mr. W. Hibberdine, Mr. A. R. Hardie, Mr. G. C. Jack, Mr. T. A. Bullock, Mr. C. Johnson, and the equerries in attendance on the Royal guests.

The evening fête was a complete success, and was ,happily, not marred by a single accident.

The officials of the Imperial Institute, upon whom devolved the work of organisation of this magnificent gathering, were assisted by Mr. G. Draper, the secretary of the Eastern Company; Mr. F. E. Hesse, secretary of the Extension Company; Mr. H. A. C. Saunders, electrician-in-chief; Mr. W. T. Ansell, traffic superintendent; Mr. W. Hibberdine, traffic accountant; Mr. A. R. Hardie, accountant of the Eastern Company; Mr. G. C. Jack, accountant of the Extension Company; Mr. T. A. Bullock, superintendent of the London offices of the Associated Companies; while Messrs. Macmillan, Brodrick, and Porter, of the Associated Companies, acted as assistant stewards.

Only those who were present can form any idea of the precision with which the arrangements devised by these gentlemen worked, and every credit is due to them for the admirable manner in which they discharged their important duties.

Telegrams were dispatched by the Prince of Wales during the evening to the Viceroy of India as follows:—

"The twenty-fifth anniversary of the establishment of Submarine Telegraphy to the Far East is being celebrated at the Imperial Institute to-night, and taking as I do a great interest in such an important work, I desire to offer my congratulations to Your Excellency on the auspicious event, and to express the hope that its usefulness in bringing the nations into closer contact and in developing commerce may be largely increased and extended in the future."

To the Governor-General of Canada, and the Governors of Cape Colony, Hongkong, Natal, New Zealand, New South Wales, Queensland, Singapore, South Australia, Tasmania, Victoria, and Western Australia as follows:—

"I am to-night present at the Imperial Institute taking part in the Celebration of the Twenty-fifth Anniversary of the Establishment of Submarine Telegraphy with the Far East; and as the Institute has been placed in direct communication with your Excellency for the occasion, I desire to offer my congratulations on the auspicious event, and to express the hope that Submarine Telegraphy will be found as beneficial in the future as in the past in helping to cement the ties binding the Colonies to the Mother Country, and in developing and extending Commerce throughout the World."

And to the British Ministers at Lima and Valparaiso as follows:—

"The Eastern Telegraph Companies are to-night celebrating at the Imperial Institute the Twenty-fifth Anniversary of their career, and taking as I do a deep interest in their great work, and the well-being of Her Majesty's subjects in all quarters of the globe, I offer you and the British Community in Chili my congratulations on an event of such importance to the world at large."

Answers to these telegrams were received in a few minutes. Governor Duff from Sydney replied:—

"I beg to acknowledge the receipt of your Royal Highness's gracious telegram, and assure your Royal Highness that the advantage of telegraphic communication with the Mother Country in developing the resources of this colony is much appreciated by Her Majesty's loyal subjects in New South Wales."

The Earl of Kintore, Governor of South Australia, replied:—

"I most gladly avail myself of the opportunity afforded me in acknowledging your Royal Highness's message, just received, to ask your Royal Highness to express to Sir John Pender and the Board of Directors of the Eastern and Eastern Extension Telegraph Companies how entirely, in common with all South Australians, I desire to associate myself in the congratulations they are receiving from your Royal Highness at the brilliant gathering assembled to celebrate the Twenty-fifth Anniversary of the Establishment of Submarine Telegraphy with the Far East, and to testify to the happy and far-reaching results of an enterprise which has done so much to promote the unity and well-being of the Queen's empire."

His Excellency the Governor of New Zealand cabled:—

"I respectfully reciprocate the congratulations of your Royal Highness on the Twenty-fifth Anniversary of the Establishment of Submarine Telegraphy. The development of this colony during that period has been great. It appreciates the assistance of the Companies and wishes them continued success."

SUMMARY OF THE PROGRESS OF SUBMARINE TELEGRAPHY.

The early history of submarine telegraphic communication between Great Britain and the Far East is especially noteworthy from the fact that it was fostered and assisted by the British Government. In August, 1858, the Red Sea and Telegraph to India Company was registered with a capital of £800,000, and a British Government perpetual guarantee of 4½ per cent. on its capital provided the cables worked throughout. The cables were laid down the Red Sea and round the coast of Arabia to Kurrachee, starting from Suez and calling at Cassire, Suakim, Aden, Hellania, and Muscat.

These cables, which were manufactured by Newall and Co., worked throughout for a very short time, but then failed and were abandoned. The British Government being obliged to continue the interest, the stock was converted into terminable annuities for fifty years from August, 1858, to July, 1908, so that the Government are still paying interest on this stock, and the total loss to the country will be altogether £1,800,000. At this time the telegraphic communication between Egypt and Great Britain was dependent upon the land line through Turkey and across the Continent of Europe. The Telegraph to India Company also had a monopoly for working the land line in Egypt between Alexandria, Cairo, and Suez.

In 1861 the first cable was laid between Malta and Alexandria *via* Tripoli, Bengasi, along the African coast. This cable was the property of the British Government, and was leased to Messrs. Glass, Elliott, and Co., afterwards the Telegraph Construction and Maintenance Company. Malta had previously been connected with Italy by the cable of the Mediterranean Extension Telegraph Company, a dividend of 3 per cent. per annum upon its capital being guaranteed by the British Government. In 1868 the Anglo-Mediterranean Company was formed to take over the Malta-Alexandria cables, and also to work a land line through Italy. An additional cable direct between Malta and Alexandria was laid, and from this nucleus has sprung the present enormous system of the Eastern and Eastern Extension Telegraph Companies.

The agitation for a direct submarine telegraphic communication between India and Great Britain culminated in 1869 in the registration of the following Companies :—

The British Indian Company, formed to acquire the rights in Egypt of the telegraph to India Company, and to lay direct cables between Suez, Aden, and Bombay. The Marseilles, Algiers, and Malta Company, formed to lay cables between Marseilles and Malta, touching at Bona; and 25 years ago the Falmouth, Gibraltar, and Malta Telegraph Company was registered. This Company accepted messages direct from the public in Great Britain, and by means of a leased land line between London and the Land's End, and cables from Land's End to Lisbon, Lisbon to Gibraltar, and Gibraltar to Malta, completed direct submarine telegraphic communication between Great Britain and its Eastern possessions. It is worthy of note that none of these companies were assisted by any Government monopolies, subsidies, or guarantees, as in the case of the original Red Sea cables, so that it may truly be said that the Government and mercantile communities of the world owe the vast benefits that they have received from direct submarine telegraphic connection during the past 25 years entirely to the enterprise of a few British merchants and the original shareholders in these Companies, who willingly risked their money in an undertaking which at the time appeared to be a speculation of a most uncertain character.

The extension of submarine telegraphic communication to countries beyond India had been proposed as far back as 1859-60, and in November, 1860, an expedition left London on board the ss. "Queen Victoria" to lay, on behalf of the British Government, a cable between Rangoon and Singapore. Unfortunately, the ship was wrecked in the Channel, and the idea of laying the cable was afterwards abandoned.

The revival of submarine telegraph enterprise in 1869, mainly caused by the successful laying and working of the Atlantic cables of 1865 and 1866, did not stop with extending the benefits of submarine cables to our Indian Empire; but large British colonies and foreign dependencies beyond India were not overlooked, and on October 20, 1869, was registered the British Indian Extension Company for laying cables between Madras and Penang and on to Singapore. The China Submarine Company was established on December 11, 1869, to lay cables between Singapore and Hong Kong and Shanghai, and the British Australia Telegraph Company was registered on January 4, 1870, for the purpose of connecting Singapore and Batavia. Batavia was connected by land-line with Banjowangie, from whence a cable was proposed to be laid to some point on the Australian coast. The companies having been duly formed, no time was lost in manufacturing the cables and submerging them.

The ss. "Great Eastern" laid the Suez-Aden section, and the line between Suez and Bombay was opened for through traffic on March 26, 1870. On June 11, 1870, the Falmouth, Gibraltar and Malta Telegraph Company opened its London office, and messages were for the first time sent direct from Great Britain by submarine telegraph to India. Countries beyond India were connected by telegraph on the following dates :—

Penang	January 4, 1871.
Singapore	December 16, 1870.
Hongkong	June 10, 1871.
Saigon	July 31, 1871.
Java	November 19, 1870.
Australia	October 21, 1872.

It will thus be seen that all the lines except that to Australia contemplated by the seven Companies formed in 1869 and the beginning of 1870, were laid and open for traffic by the middle of 1871. As regards the line to Australia, the cable was laid on November 22, 1871; but, owing to the non-completion of the Australian land lines and a long interruption of the Banjoewangie-Port Darwin cable, telegrams were not able to pass uninterruptedly between Europe and Australia until October 21, 1872. This long system having been fairly started as a commercial enterprise, it was impossible for it to stand still, and the watchword of its promoters has ever been "Onward!" so as to extend the benefits of submarine telegraphy to all parts of the known world.

After the seven companies had been working a short time it was found desirable to amalgamate the four Companies owning the cables this side of India into one Company, and on June 6, 1872, the Eastern Company was registered, and took over the Falmouth, Gibraltar, and Malta, the Marseilles, Algiers, and Malta, the Anglo-Mediterranean, and the British Indian Submarine Companies, and this having been successfully accomplished, the Eastern Extension, Australasia and China Telegraph Company was registered on April 24, 1873, and absorbed the British Indian Extension, the China Submarine, and the British Australian Telegraph Companies. It is, therefore, more than 20 years ago that the system of submarine telegraphs which had been inaugurated in 1869 assumed the form under which they have been so successfully worked up to the present time.

During the first few years of the working of the Eastern submarine telegraphs, several prolonged interruptions of communication took place. The Lisbon-Gibraltar cable was interrupted from November 28, 1870, to February 11, 1871, and again from April 27 to September 30, 1871. During this time telegrams to the East had to be sent from England *via* Holland, Germany, Switzerland, and Italy to Malta, the route through France being unavailable owing to the Franco-German war and the Paris Commune. The next serious interruption of communication this side of India was that of the Suez-Aden cable from November 15, 1875, to February 2, 1876. The communication between Aden and Bombay has been totally interrupted on three occasions, viz. :—

July 13, 1881, to August 9, 1881.
June 3, 1884, „ June 27, 1884.
Aug. 11, 1888, „ Sept. 11, 1888.

The only other serious total interruption this side of India was during the Egyptian war, when the land lines in Egypt were unavailable for our through traffic from July 11, 1882, to September 29, 1882. The most serious total interruptions beyond India have been as follows :—

Madras-Penang	Nov. 14, 1875, to Dec. 24, 1875
„ „	Mar. 27, 1876, „ Oct. 25, 1876
„ „	June 13, 1884, „ July 14, 1884
Java-Australia	June 25, 1872, „ Oct. 21, 1872
„ „	Nov. 8, 1877, „ Dec. 15, 1877
„ „	Sept. 27, 1878, „ Nov. 2, 1878
„ „	July 4, 1879, „ July 24, 1879

The inconvenience of these total interruptions to the Governments and telegraphing public, as well as the loss of revenue sustained by the Companies showed the management the absolute necessity of duplicating and triplicating the communications. This was carried out on the following dates :—

Duplicate Cable.	Date of Laying.
Portheurnow-Lisbon, *via* Vigo	July 19, 1873
Lisbon-Gibraltar, *via* Villa Real	Sept. 27, 1871
Gibraltar-Malta	Oct. 12, 1887
Malta-Marseilles	Oct. 24, 1887
Malta-Alexandria	Nov. 22, 1870
Alexandria-Suez, *via* Port Said	Aug. 25, 1882
Suez-Aden	Nov. 11, 1876
Aden Bombay	Mar. 7, 1877
India-Penang, *via* Rangoon	Apr. 7, 1877
Penang-Singapore, *via* Malacca	Aug. 15, 1879
Singapore-Hongkong *via* Labuan	May 4, 1894
Singapore-Java (Banjoewangie)	Dec. 9, 1879
Java-Port Darwin	Jan. 28, 1880
New Zealand-Australia	May 7, 1890
Victoria-Tasmania	Nov. 23, 1885

Digitized by Google

Triplicate Cable.	
Porthcurnow-Lisbon	July 21, 1887
Lisbon-Gibraltar	July 27, 1887
Suez-Aden	Apr. 21, 1883
Aden-Bombay	Apr. 19, 1891
Penang-Singapore	Apr. 10, 1892
Java-Australia (*via* Roebuck Bay)	Feb. 26, 1889
Quadruplicate Cable.	
Suez-Aden	Nov. 18, 1890

It should be mentioned that the Australian Colonies, appreciating the benefits of continuous communication, and admitting the fact that the Company single-handed was unable to carry out the system of duplication, generously assisted the Eastern Extension Company by granting a subsidy of £32,400 per annum. With this exception the whole of these additional lines have been laid at the sole expense of the two Companies.

The communication with the East has been further strengthened and improved by the leasing of a line between London and Marseilles, through France, over which passes at the present time the principal portion of the traffic between Great Britain and the far East, by a direct cable between Malta and Zante, and by joint purse agreements with the Indian Government, the Indo-European Telegraph Company, and the Great Northern Telegraph Company. By means of allied companies South America has been connected with Europe, and the continent of Africa has been practically surrounded by submarine cables.

The system of submarine telegraphs which is generally known under the name of the "Eastern" may truthfully be said to be one of the greatest monuments of British enterprise and perseverance that the world has ever seen, and it has ever been the endeavour to go forward, never being satisfied with its present efficiency, but always striving to do better than before.

A few instances of the average time occupied in transit of the general traffic may be interesting:—

	Opening of Line.	Present Day.
Portugal	5 to 6 hours	30 mins.
Spain	9 to 10 „	15 „
Egypt	3 to 4 „	20 „
India	5 „	35 „
China	8 „	80 „
Australia	10 „	100 „
Brazil	8 „	25 „
Argentine	10 „	60 „
Chili	10 „	70 „
Peru	10 „	80 „

The two Companies and their allies employ nine ships, which are constantly at work repairing the cables and keeping up communication, besides which tanks for the storage of cable have been erected at many places on the Companies' system, and it is worthy of note that although the opinion of experts varies considerably as to the life of a submarine cable, these two Companies have never been unable to repair a cable, and the original lines are capable of carrying the same amount of traffic at the present time as on the day they were laid.

One of the greatest improvements which the Companies have been able to avail themselves of was the introduction of the patent for duplexing the cables whereby, their carrying capacity has been increased by at least 75 per cent. By reducing delay we create traffic, because if merchants can obtain a reply to their morning message in the same day they can send the answer before the close of business hours; indeed, in many cases three or four telegrams are exchanged between London and abroad during the six or seven hours of the day that business is carried on in the City.

When the Companies were started 25 years ago the system of code messages had not been invented, and the estimate of receipts was based upon all telegrams being sent in open language; if this estimate had been maintained the revenue of the Companies would have been very much larger than at present; but it is only fair to say that the existing cables would not have been able to carry the traffic. On the complete opening of the lines the cables carried 425,000 messages per annum; at the present time they are carrying 2,100,000; the average length of the telegrams is now, however, only 11 words, whereas it used to be 35 words. The two Companies and their allies now work 124 stations, against 25 at the time of opening of communication.

Tariffs.—The general system of tariffs in vogue twenty-five years ago was a charge based upon a message of twenty words, with a proportionate increase for every extra ten words. This system lasted until 1876, when the alterations agreed to at the St. Petersburg conference were brought into operation, and all messages exchanged with places outside Europe were charged at a tariff of so much per word. This system had been partially tried with India as far back as November, 1873, but with this difference, that a minimum charge was made for the first ten words.

When the submarine cables were first opened for international correspondence with India they had to compete with the existing overland line of the Indo-European Company through Germany, Russia, and Persia to Bushire, and thence by the Indian Government cables to Kurrachee. The tariff was £2. 17s. per twenty words, but it was soon found that the rate was quite inadequate to pay expenses, and a fair dividend on the capital invested by either route; and after a sub-conference of the States interested, held at Berne, the rate was raised to £4 per twenty words on January 1, 1871. This rate was again raised in February, 1871, to £4. 10s., and lowered to £4 in July, 1872, and after some variations it was fixed at its present figure of 4s. per word in July, 1886. Experience has shown that this is a fair rate for the Indian business, which is not an expensive one, and the traffic has practically remained stationary for many years.

The tariffs with European countries are governed by the charges *viâ* the land lines, and it may be said that wherever we have been brought into competition with the Government land lines the Companies have managed to hold their own, and to secure the principal portion of the traffic. There is nothing worthy of particular notice in the tariffs to the Far East, with the exception of those for messages exchanged with Australasia. After prolonged negotiations the rates between Europe and Australasia were reduced from 9s. 4d. to 4s. per word, under a guarantee from the Governments, the Companies taking upon themselves half the risk; the result was an increase of 50 per cent. in the number of words carried, and a gross loss of revenue equal to £55,000. In January, 1893, the rate was raised at the request of the Colonies to 4s. 9d. per word, but, owing principally to the great depression of trade in Australasia at the present time, the increase of traffic over that carried at the tariff of 9s. 4d. is not so large as might be expected.

Some years ago the Companies, with a desire to supply the general public with cheap news, introduced with this object reduced press rates, not only for supplying European news to the countries in the East, but also to enable the European public to obtain news of the doings of their friends beyond the seas. The experiment has as a whole proved satisfactory, and the Companies are always willing to extend the system wherever practicable.

In concluding, it may be pointed out that the telegraph rates for messages exchanged with the East have during the past 25 years been fair ones, not only for the Companies carrying the traffic but also for the public. The results have been different from the experience of the North Atlantic Companies; the latter, owing to competition and insufficient tariffs, are at the present time not in the position to give their shareholders a fair dividend on the capital invested.

A *résumé* of the history of submarine telegraphs to the East would not be complete without mentioning a few of the events of international interest in which the telegraph has played an important part. The Earl of Mayo was murdered in the Andaman Islands, and the news was confirmed by a special message brought through the submarine telegraphs in a few minutes (February, 1872). During the war in Afghanistan in 1878, 1879, and 1880 the Government made large use of the telegraph, and the British public was enabled to read full details of all actions almost as soon as they took place. The disaster of Isandula in January, 1879, was not known in Great Britain until some weeks after it happened, owing to the want of submarine telegraph communication, and this event probably more than anything else hurried on the negotiations for the opening of telegraphic communication with South Africa.

In 1881 all the negotiations with the Transvaal were carried on by means of the telegraph, so that the British Cabinet was practically in hourly communication with the Boer leaders. But the event which more than anything else exemplified the capabilities of the telegraph, and proved to the world at large the enormous difference in the transmission of news in the present day compared with what it was twenty-five years ago, was the bombardment of Alexandria and the subsequent operations in Egypt, the Soudan, and Suakin. It is not too much to say that during this time the public were kept in hourly touch with all the events, even to the minutest detail, that were happening in Egypt, and the Eastern Company is justly proud that the immense traffic at that time was brought through without practically any delay at all, and it most certainly reflects great credit on the management that had created a system so perfect that an influx of such an enormous traffic affected it to such a slight extent.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 846.—Vol. XXXIII. FRIDAY, AUGUST 3, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

The interest of the electrical profession in the proceedings of the British Association, although most commonly directed chiefly to Section A, seems likely this year to be about equally divided between Sections A and G, or even to preponderate on the side of the latter. We are able to forecast, to some extent, the proceedings of these two Sections. The electrical Papers in A will include a contribution by Lord Kelvin and Dr. Magnus Maclean on air electrification; a Paper by the former conjointly with Mr. Galt on some conditions of Leyden-jar discharge; one by Dr. Stoney, entitled "How the Misuse of the word Force in Attractions in Electricity and Magnetism may be Avoided without much Departure from Existing Practice." This last may possibly give rise to some discussion on the foundations of dynamics, and the metaphysical aspects of the word Force. Poor word! It has served its time very faithfully; may it be well pensioned when the time comes for it to go! Prof. Viriamu Jones will give some descriptions of his further researches on standards of resistance; and Prof. Schuster will contribute two Papers—one on terrestrial magnetism, the other on the construction of sensitive galvanometers. A Note by Mr. Newall on the spectra of discharges in gases without electrodes ought to prove of interest to students of molecular physics.

The regular electrical day for Section G is fixed for Monday, August 13th. Mr. Preece will contribute two Papers—one dealing with the efficiency of glow lamps, the other on signalling without wires. A direct-reading platinum pyrometer will be described by Mr. G. M. Clark. The system of electric supply at Oxford will be described in a Paper by Mr. Thomas Parker. Besides these directly electrical contributions, electrical engineers should find interesting material in the Paper on engine hunting which Mr. Swinburne will read; in a Report by the Committee on the dryness of steam; in Mr. Burstall's Paper on entropy; and in a Paper which Prof. Hudson Beare will read on "Steam Losses." Prof. Kennedy's presidential address to this section will discuss the subject of "Modern Mechanical Training, Constructive and Critical." The fusion of Sections G and A into an alloy, on Friday, August 20th, will be looked for with interest, as it is expected to be attended with the liberation of considerable amounts of energy. On that occasion two important discussions are arranged to take place: one on "Integrators, Harmonic Analysers, and Integraphs, and their Application to Physical and Engineering Problems," which will be opened by Prof. Henrici; and the other on "Flight," to be led off by Lord Kelvin and followed up by Mr. Maxim and other authorities.

We learn with some alarm that Lord Kelvin and Lord Rayleigh recently "assisted" at an experimental run of Mr. Maxim's flying machine. It may be true that guard rails were fixed to prevent any serious rise into the air, but could not these distinguished visitors have been content to watch the performance at a safe distance? If mere ballast was wanted, copies of their collected works might have been used. If Mr. Maxim must needs have a living cargo of well-known men, we shall be happy to supply him with the names of two or three men who could be spared, and who never would be missed. We cannot afford to lose Lord Kelvin and Lord Rayleigh.

The report of the Directors of the Liverpool Overhead Railway Company for the half-year ended June 30th shows that this concern continues to prosper. To pay the Preference shareholders in full, and the Ordinary shareholders at the rate of 1 per cent., is by no means a bad record for a novel type of railway that only came into operation a year ago last March. The following comparative figures for the half-year may be of interest. The "loco." expenses of the Liverpool line not comprising the items of salaries and wages for repairing work, these have been deducted from the London total.

	Liverpool.	City and South London.
Passengers carried	2,861,437	3,383,154
Train miles run	265,349	227,363
Passengers per train mile	11	15
Passenger receipts per train mile...	17¾d.	24¾d.
"Loco." expenses per train mile...	2¾d.	5¾d.

The results of practical every-day use of electric welding formed the subject of a Paper read by Mr. B. A. Dobson, of Bolton, before the Institution of Mechanical Engineers at Manchester on Tuesday last. The author has found the system to be very satisfactory on the whole, but the chief advantage is the uniformity and reliability of the work rather than any saving in cost. The extravagant promises made a few years ago have not been realised, and the onerous terms of licence and the cost and depreciation of the plant have, as seemed likely from the first introduction of the process into this country, greatly impeded its development. In the discussion which followed, the general opinion was that the process could only be worked advantageously in special

Digitized by Google

cases in very large establishments. Electric welding by the Thomson process seems to be most valuable where it is worth while to build a machine for one definite and invariable job, and where it can be employed continuously. The smaller the work, down to, say, No. 22 wire, the more useful and satisfactory is the process, and, similarly with the Benardos process, the thinner the sheet the more remarkable are the results.

The gist of Mr. Thornycroft's interesting Paper on "The Influence of Circulation on Evaporative Efficiency of Water-Tube Boilers" amounts to the following:—That if a high evaporative efficiency is desired, rapid circulation must be promoted; that rapidity of circulation cannot be obtained unless a separate down-take for the water is provided; and that any constriction of the water in its passage through the down-take must reduce the effective head tending to lift the water in the heating tubes, and will therefore hinder circulation. Mr. Thornycroft's experiments amply bear out these conclusions, which, we may add, are perfectly consistent with the established theories of circulation and evaporative efficiency. His discovery of the critical point in certain cases will, however, be an important item of news to many boiler makers, and may lead to more scientific practice in the future. Water-tube boiler makers are in some instances also inclined to forget that constriction of the downtake is not simply a matter of sectional area of the return tubes. We could mention more than one example of well-known boilers having an imperfect circulation, even with ample section of downtake, the defect arising from the irregular motion given to the water in its passage from the steam vessel to the water vessel. Some of the speakers in the discussion on Mr. Thornycroft's Paper appeared to condemn over-circulation, as being liable to cause over-heating. Over-circulation, *per se*, cannot do any harm; in fact, it is an impossibility. What is harmful is the attempt to crowd too much heat through each square foot of heating surface. This will, of course, produce extra rapid circulation; but it is not the rapid circulation which does the mischief, it is the lack of proper heating surface. The same amount of circulation in a different boiler might prove perfectly harmless.

Not one of the least important services which Mr. Crompton has rendered to electrical engineers, in his recent Paper on "The Cost of Electrical Energy," is the emphasis he has laid on the importance of minimising the losses which occur in auxiliary plant at central stations. The use of small supplementary steam-engines for driving the feed-pumps, or the automatic stokers, is a case in point. These engines, even when worked at full load, cannot be as efficient as large engines; while, as is very well known, the greater part of their time is filled up on small fractions of full load or in absolute idleness, during which time they are "eating their heads off," as it were, owing to the enormous condensation of steam which takes place. Mr. Crompton has already discovered that it is more economical to take this auxiliary power from the main engines, even though through the intermediate mechanism of the dynamos, some yards of cable, an electro-motor and a belt, than to derive it from a special small engine. Mr. Bromley Holmes now informs us that he has adopted this practice for driving the mechanical stokers for the boilers at the Liverpool electric supply station, and kindly sends us some particulars of the arrangement. A 1-h.p. electric motor, run from the station mains, is geared to a countershaft by means of a belt, and a second belt placed between the countershaft and the stoker shaft transmits the power to the stoker. As the variations of speed necessary to the regulation of the coal feed are effected in the stoker mechanism itself, the motor may be run continuously at its normal speed. When the stoker is not at work the cutting of the motor out of the circuit obviates any stand-by losses. The arrangement is, therefore, almost as efficient at low loads as at full load, and is found in practice to give very satisfactory results.

It is a truism that the design, and especially the width, of the streets of a city reacts upon the nature of the means of locomotion. This being the case, the future of electric and other vehicular traffic in London is not unconcerned with the provisions in the new Bill of the London County Council regulating the width of London streets. In regard to the item of width, the *Builder* characterises the provisions as miserable, and "calculated to stereotype one of the greatest mistakes that can be made in a town, both for appearance and for sanitary conditions." The standard L.C.C. street of the future, it appears, is, if the Bill comes into force, represented by Chancery-lane. Compare the proportions of the narrow slot which bears this name with the ample proportions of High Holborn, or the spacious width of Portland-place, and it will readily be seen that London of the future will, to say the least of it, know very little of the electric trolley. Probably the increased surface pressures will tend to induce the citizens to travel more frequently underground, and the modification of street design will become the pre-disposing cause for an even greater number of tubular electric railways than are now under contemplation. Yet where is the need for such Chinese density of population? What adequate compensation do the proposed changes offer for the loss of æsthetic and hygienic advantages in our wider streets? What would Paris become, for example, under the ægis of such street reformers?

Portrait of Heinrich Hertz.—A Steel Plate Portrait of the late Dr. H. Hertz will be published with our next issue.

Cable Interruption:

	Date of Interruption.
Para-Maranham...	July 23rd.

Douglas and Laxey Tramway.—The new coast electric tramway between Douglas and Laxey was formally opened to the public on Saturday.

Accumulator Manufacturing in Spain.—It is reported that large works for the manufacture of accumulators are about to be established at Linares.

Professional Appointment.—Herr E. Arnold, chief engineer to the Oerlikon Works, has been appointed professor of electricity at the Technical High School at Karlsruhe.

The Telegraph in South Africa.—The telegraph line from Tati to Buluwayo, a distance of 108½ miles, has been constructed in 133 days, and at the cost of under £3,400.

Owen's College, Manchester.—A special course has been arranged on "The Technical Applications of Electricity." Further particulars will be found in our advertising columns.

Digitized by Google

Lord Kelvin.—The Société d'Encouragement has awarded its grand gold medal for 1894 to Lord Kelvin. This medal is awarded to Frenchmen or foreigners whose labours have had the greatest influence during the preceding six years on the progress of French industry.

Chelmsford.—The arc lighting mains in the streets of Chelmsford, which were originally carried overhead, are now being placed in underground conduits, and the poles which were formerly used are being removed. The inhabitants are anxious to have the disused gas lamps also removed.

Telegraph Posts and Advertisements.—The City Council of Wellington, New Zealand, has passed a resolution "that the Government be requested to keep the telegraph posts free from advertisements, in view of the bye-law passed by the Council, which forbids the placing of advertisements on the electric light posts."

Model Answers.—In a set of model solutions to South Kensington examination questions, given by a contemporary, the question: What is a slide-valve? is answered as follows—"A slide-valve is a hat-shaped box, rectangular in plan, whose under surface is truly plane." Did the writer ever see a real slide valve?

Liverpool University College.—Notice is given by the Department of Engineering that the session 1894-95 commences on October 2nd next, when complete courses of instruction are arranged in civil, mechanical, and electrical engineering. Further particulars will be found in our advertisement columns, and prospectuses and all information can be obtained on application to the registrar.

The Institution of Civil Engineers.—The three houses, Nos. 24, 25, and 26, Great George-street, Westminster, S.W., are being rebuilt, and it is hoped that in about 18 months the new premises will be complete. The library has been removed to No. 9 opposite, where the temporary offices of the Institution are situated. The meeting-room will probably remain untouched until after next session, access being given from the street by a temporary way.

The Municipal Working of Tramways after Purchase.—At the meeting of the London County Council on Tuesday last the Highways Committee recommended that application be made to Parliament for powers for the Council to work, should it be deemed necessrry or expedient, any tramway which it might purchase under the provisions of the Tramways Act, 1870, or of any other Act; and that it be referred to the Parliamentary Committee to take all the necessary measures for the purpose.

The Epping Forest Electric Railway.—The Select Committee of the House of Lords, which had already passed the preamble of the London, Walthamstow, and Epping Forest Railway Bill, on Tuesday went through the clauses. An agreement was scheduled to the Bill with reference to the manner in which the railway is to be constructed through the estate of Mr. Bros, at Upper Clapton, and, with this amendment, the Bill was ordered to be reported. The scheme has now received the sanction of both Houses.

The Meeting of the Canadian Electrical Association.—The next convention of this Association will be held in Montreal the latter part of September, and will be one of unusual interest. The date of the convention will, if possible, be arranged to suit the usual autumn railroad excursions to Montreal and Quebec. The meetings will extend over three days. The following are some of the Papers which will be read: "The Possibility of Securing Better Regulation at Central Light and Power Stations by means of Fly-Wheel Accumulators of Improved Construction," by Mr. John Galt; "A Method of Distribution with Equalisation of Potential Difference," by Mr. D. H. Keeley, of the Government Telegraph Service, Ottawa; "Electrolysis," by Mr. J. A. Baylis; "Telephone Cables, their Construction and Maintenance," by Mr. F. J. F. Schwartz; "Alternating Motors," by Mr. L. M. Pinolet.

The City Telephone Tubes.—At the meeting of the City Commissioners of Sewers on Tuesday last Mr. Pannell moved: "That the resolution of this Court, of July 25, 1893, agreeing to a recommendation of the Streets Committee, that the Commissioners only consent to the use for telephonic purposes of certain tubes laid by the City of London Electric Lighting Company, on a guarantee being given that telephones with double wires and all the latest improvements will be supplied to the citizens at a cost not exceeding £8 per annum, be rescinded." Mr. Pannell said that the present position in which the Court was placed was a very undesirable one. The tubes which had been the subject of dispute were underground, and they represented a capital of between £80,000 and £100,000. The Commission had received an offer whereby the rates could be benefited, while it was possible also that the users of telephones would be the recipients of benefits; but as long as the present block existed the Court was simply playing into the hands of the National Telephone Company.—The motion was carried by 33 to 16.

City and Guilds of London Institute.—The Council of the City and Guilds of London Institute have conferred the Fellowship of the Institute upon Dr. W. E. Sumpner, who was awarded the Diploma of Associate of the Institute in 1887, and has since by many original and valuable researches contributed to the advancement of the electrical industry. The Council have also conferred the Diploma of Associate upon the following matriculated students who have this year successfully completed the full course of instruction at the Central Technical College:—*Civil and Mechanical Engineering:* Abbott, N., Aldis, B. S., Bushell, C. L., Carter, R. B., Cautley, A. O., Hall, A. C., Hallett, A., James, J. H., Lightfoot, C., Lloyd, H. G., Maeers, F., Stubbs, B. T., Thomas, W. *Applied Physics and Electrical Engineering:* Abrahamson, M. A., Bowden, J. R. J., Day, P. J. C., Fullerton, R. A., Harris, A. F., Leake, H. C., Mayes, A. E., Mentheth, W. F. S., O'Gorman, M. J. P. Robinson, L. L., Severs, J., Taylor, A. K., Ward, J. A. W., Wood, R. J. C. *Applied Chemistry:* Crighton, A. M., Marshall A., Schwabe, E. W. S.——At the session of the Court of Common Council, last Thursday week, the Lord Mayor presiding, a grant of £500 per annum for three years, to be made to the City and Guilds of London Institute, was recommended by the Finance Committee and was adopted.

Electric Lighting on the Embankment.—At the meeting of the London County Council on Tuesday last the Highways Committee referred to reports which had been approved by the Council recommending the establishment of an electric installation for the lighting of the Victoria Embankment at a capital cost of £10,000, while the cost of maintenance would probably not exceed £2,000 per annum. Subsequently the lighting of Westminster and Waterloo bridges and the Embankment-gardens was included, and the capital expenditure was increased to £15,000. The scheme contemplated that lamps of from 1,000 to 1,200 c.p. should be placed in the centre of the carriage-way about 50 yards apart. In March the Council decided that it was undesirable to place any lamps along the centre of the roadway. This resolution involved a reconsideration of the whole scheme, and instead of a total number of 108 lamps, as originally anticipated, by the adoption of side lighting 136 lamps would be required. The cost of the buildings and machinery would also be more than the Committee anticipated. Moreover, the period for the repayment of the loan had been reduced from 40 years to 25. They accordingly submitted a recommendation increasing the estimate to £20,000. Mr. Westacott moved that consideration of the report be deferred till next spring, as the lighting would not be available for next winter, and this was agreed to.

The Government and the Telephones.—In reply to questions addressed to him in the House of Commons this week, Mr. Arnold Morley said: "I think it may be said that an agreement has at last been arrived at between the National Telephone Company and the Post Office; but until the approval of the Company has been formally conveyed to me, and the sanction of the Treasury obtained, I shall not be in a position to lay the draft agreement on the table of the House. I think it right to add that some questions connected with companies controlled by the National Company must first be settled; but I have no reason to apprehend that this will involve serious difficulty or delay. I would point out that the agreement does not require the confirmation of Parliament, and I am, therefore,

Digitized by Google

not aware that any special opportunity for its consideration will be necessary; but the subject is one which can, in due course, be raised on the telegraph estimates." Mr. Henniker Heaton asked whether the Postmaster-General would undertake that the question should not be finally settled before the House had had an opportunity of expressing its opinion upon it; and whether he would also give an undertaking that if the matter came on at the end of the Session he would give a promise that the carrying-out of the agreement should be postponed till next Session. Mr. Morley replied that he could not give any such undertaking. The agreement would be laid on the table of the House before it was signed. Proper time would be given to hon. members to consider it.

Screw Threads in Germany.—It is, perhaps, not generally known among English engineers that the German manufacturers are as yet unprovided with a standard system of screw threads, "every man doing that which is right in his own eyes." We learn from a Paper read to the Elektrotechnischer Verein by Mr. Th. Peters that the Imperial GermanNavy uses a thread cut to the Whitworth standard, but the dimensions made to the nearest whole millimetre; while the Royal Prussian railways use another variant of the Whitworth system; while yet a third variation of the Whitworth thread is in use in the War Department of the Prussian Government. The Verein Deutscher Ingenieure has, since 1875, been striving to bring about the adoption of some standard system, and in 1888 devised a metrical system of screw threads. Mr. Peters endeavoured to obtain from the Elektrotechnischer Verein a definite adoption of this system, but the Society preferred to adopt the following resolution: "The Elektrotechnischer Verein resolves to join the Verein Deutscher Ingenieure and the Verein der Präcisionsmechaniker in their endeavours to secure the adoption of a standard metrical screw thread," and thus avoid committing themselves to any definite system.

Glasgow.—The following additional information with regard to the working of the Glasgow municipal supply for 1893-94 will be of interest:

"Though the financial statements do not show a profit for the past year, it may be regarded as a fairly satisfactory one. A loss on the year's operations is shown, which amounts to £607. It may be mentioned that the loss on the electric lighting account in the preceding year, or rather on the operations during the period of 15 months extending from March 1, 1892, to May 31, 1893, was £1,773. It is shown by this statement that sums amounting to £120,000 had been borrowed for the electric lighting undertaking up to the end of the past financial year, and that of the amount sanctioned by the Board of Trade there was still a sum of £80,000 that might yet be borrowed. A sum of £1,200 has been paid into the sinking fund during the past financial year, and the amount now paid into that fund is set down in the statement of accounts at £2,014. For sale of current by meter during the year there was obtained a revenue amounting to £15,819, and for public lighting £1,693, the gross total revenue being £18,016. From the revenue account it is seen that the actual expenditure on the generation and distribution of electricity, attending and repairing public lamps, on royalties, rents, rates and taxes, and on management expenses, &c., was £9,592; the sum of £4,393 is set down as depreciation on works, machinery, mains, &c., and those two sums give a total of £13,985, the deduction of which from the revenue of £18,015 previously mentioned gives a balance of £4,031, which is carried to profit and loss account. The sum of £3,438 is set down in the profit and loss account as interest on loans, &c., and to it there is added the sum of £1,200, being the amount carried to the sinking fund; and these two items give a total of £4,638. When the gross profit, or balance of £4,031, brought from the revenue account, is deducted from the amount just named, there is the net balance of £607. The amount generated was 854,766 Board of Trade units, and the total quantity sold was 702,248 units. On the works there were used 13,326 units so that the total quantity accounted for is 715,574 units, and consequently the amount not accounted for aggregated to 139,192. The loss upon the total amount generated thus works out at rather more than 16¼ per cent.'

Postal Telegraph Staff Grievances.—In deference to the wish of many members of Parliament and others, the officials of the Postal Telegraph staff have prepared a statement of the case which they present for an amelioration of their position. They claim that "care has been taken to present both sides of the question. The official view is put forcibly and clearly by Sir James Fergusson and Mr. Arnold Morley. Elsewhere the telegraphists themselves, in petition and speech, tell what their complaints and desires are. Independent views, including those of Parliamentary and municipal representatives, those of members of public bodies and of the Press, are also given, so that the facts may be readily grasped and an estimate formed of the claims submitted." They add that "throughout the telegraph service there is a growing belief that without agitation wrongs will not be righted; that not until a full, impartial and independent inquiry has taken place will a satisfactory adjustment of the matter in dispute be possible. That the present unhappy state of things cannot much longer continue must be evident to anyone who ever glances at the facts here presented. A mere revision of salaries will not suffice. Reform of the whole system is demanded by every consideration, whether of departmental policy, of public interest, or of fairness to the telegraphists, and, if the circulation of this *resumé* helps forward such reform, the object of the Postal Telegraph Clerks' Association in issuing it will have been gained." The statement is put forward in pamphlet form.

Hanley.—The inaugural ceremony of the Hanley electric supply station took place last Thursday week. The generating station is adjoining the canal. Steam is supplied from three Lancashire boilers, each 28ft. long by 7ft. in diameter. Each boiler is fitted with all the latest improvements, being constructed for a working pressure of 140lb. per square inch, and mechanical stokers are used. Coal is landed direct from the barge on to a platform, from which it is fed by chutes into the stokers; thus is secured the utmost economy in labour and fuel. The main pipe is of wrought iron, 6in. in diameter, and forms a ring, with valves so arranged that any section may be isolated. The branches to the main engines are 4in. and 3in. The whole of the valves are of the parallel slide type, so that when open the steam has a straight passage through. The exhaust piping, which is of cast iron, ranging from 9in. downwards, opens into the condensers or direct to atmosphere as may be desired. The main engines are at present four in number—two of 200 I.H.P. and two of 100 I.H.P., and are of the well-known Brush compound vertical type. The alternators, which are of the well-known Mordey-Victoria type, are driven from the above engines by means of cotton ropes. Two of these run at 430 revolutions per minute, and have a capacity of 100 kilowatts each, whilst the other two run at 600, and have a capacity of 50 kilowatts each, the pressure being in each case 2,000 volts. The whole of the engine-room plant has been manufactured by the Brush Company. The distribution is effected by low pressure distributing mains at 100 volts, running from the transformer sub-stations, which are situated at convenient points in the town. The high-pressure feeder mains consist of concentric copper cables of 100 per cent. conductivity, highly insulated with vulcanised rubber and tape, braided with tarred hemp yarn, and compounded, and are drawn into cast-iron socket pipes, coated inside and out with preservative compound. Suitable draw-boxes are provided at intervals. The high-tension joints are of the Raworth-Geipel patent type, which have many advantages over the ordinary vulcanised rubber joints; the joints, being mechanical, are easily made and can be inspected by merely lifting off the cover; while the cable can easily be disconnected for testing. The transformer chambers are equipped with Mordey-Victoria transformers of the 18-kilowatt size. The principal streets are lighted by means of the Brush arc lamps fitted to ornamental posts, and worked from machines independently of the private supply. The by-streets are to be lighted by incandescence lamps, which are cut in by means of Lobley's patent automatic switch when the arc light circuits are started, so that the whole of the streets are lighted simultaneously by merely switching on at the generating station. There are two Brush series dynamos, each capable of developing 125 kilowatts at 8 amperes, running at 900 revolutions per minute. The arc light machines are driven by two vertical tandem type engines, having cylinders 6in. by 10in. by 8in. stroke, running 200 revolutions per minute. The arc light main consists of a cable highly insulated with vulcanised rubber, protected by prepared tape, compounded and drawn into cast-iron pipes. Geipel's patent telescopic street boxes, constructed entirely of cast-iron, are used for these mains. In conclusion it should be stated that the whole of the works have been carried out under the able supervision, on behalf of the Hanley Corporation, of Mr. Joseph Lobley, borough engineer; while the general design and equipment have been in charge of the Brush Company's Contract Department and Staff, under the control of Mr. W. Geipel.

ELECTRIC MOTIVE POWER.*

BY ALBION T. SNELL.

(*Continued from page 325.*)

Motors; and Driven Machines; Selection of Type of Motor; Continuous and Polyphase Currents; Safety Motors.

The selection of the type of motor for any special work is generally not difficult, the crux lies in estimating the average and maximum torque—an approximate estimate of the power is easily arrived at, and a small error in its determination is of little importance.

For example: suppose it is required to drive a main pump, as shown in Fig. 111, on a continuous current circuit at 500 volts pressure at the motor terminals. The theoretical power in the water is known, and the losses in rising main, pumps, gearing and motor, are easily determined. The maximum torque will occur at starting, when the motor has to overcome the statical friction of the pumps and set the column of water in motion. The average torque will be simply that due to the constant load with full delivery of water. To fulfil these conditions, it is necessary to have a motor with a magnetic field sufficiently strong to give the necessary starting torque without undue sparking or an excessive quantity of current; and to give the working load at the designed speed with the highest possible efficiency consistent with a fair margin of power.

The motor winding preferably should be in series for reasons previously given.

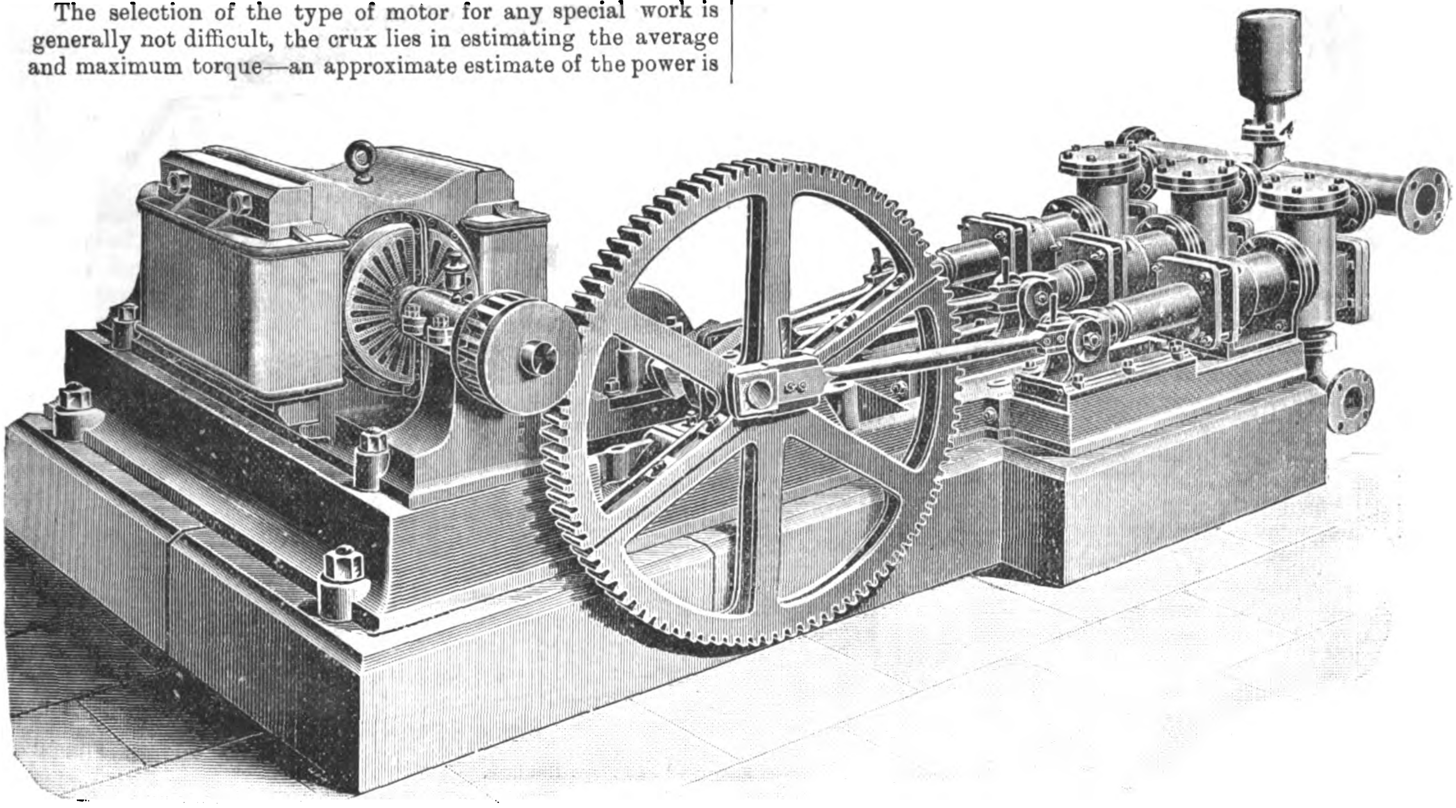

Fig. 111.—General Electric Power and Traction Company's Three-throw Main Pumps, Geared to Motor.

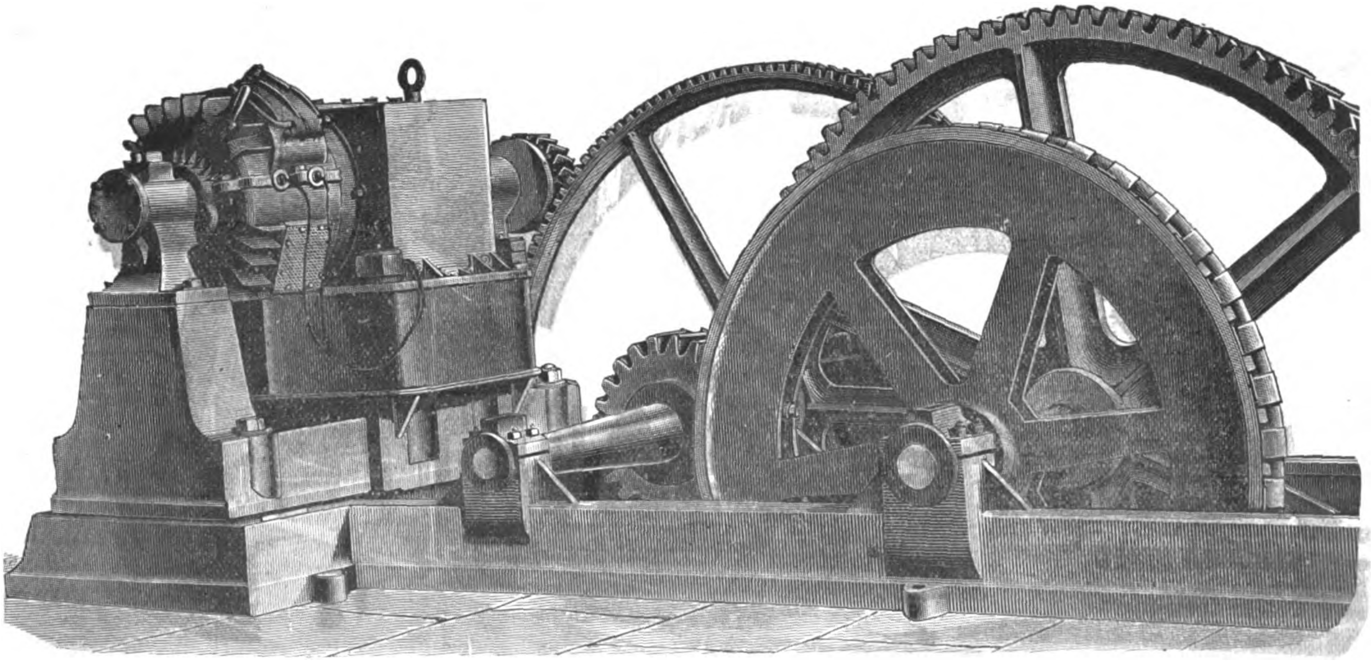

Fig. 112.—Endless Rope Haulage, with Goolden Safety Motor.

The chief constructional point is sufficient strength in the armature shaft and bearings to safely start the pumps, if this be attended to the motor will be mechanically strong enough for the running load.

Again, assume it is required to erect an endless rope hauling plant—as illustrated in Fig. 112—on the same circuit. The various losses must first be determined, the weight of tubs loaded and unloaded, debited and credited according to the grades, and a suitable allowance made for tub-wheel, and rope friction. From these data the starting and the average torque can be determined. If the running load be fairly constant—as is generally the case with an endless rope—the series wound motor is the most suitable, and the suggestions made with reference to the main pumping motor are equally applicable. The margin of power, however, requires to be greater than with pumps, as the load may be largely

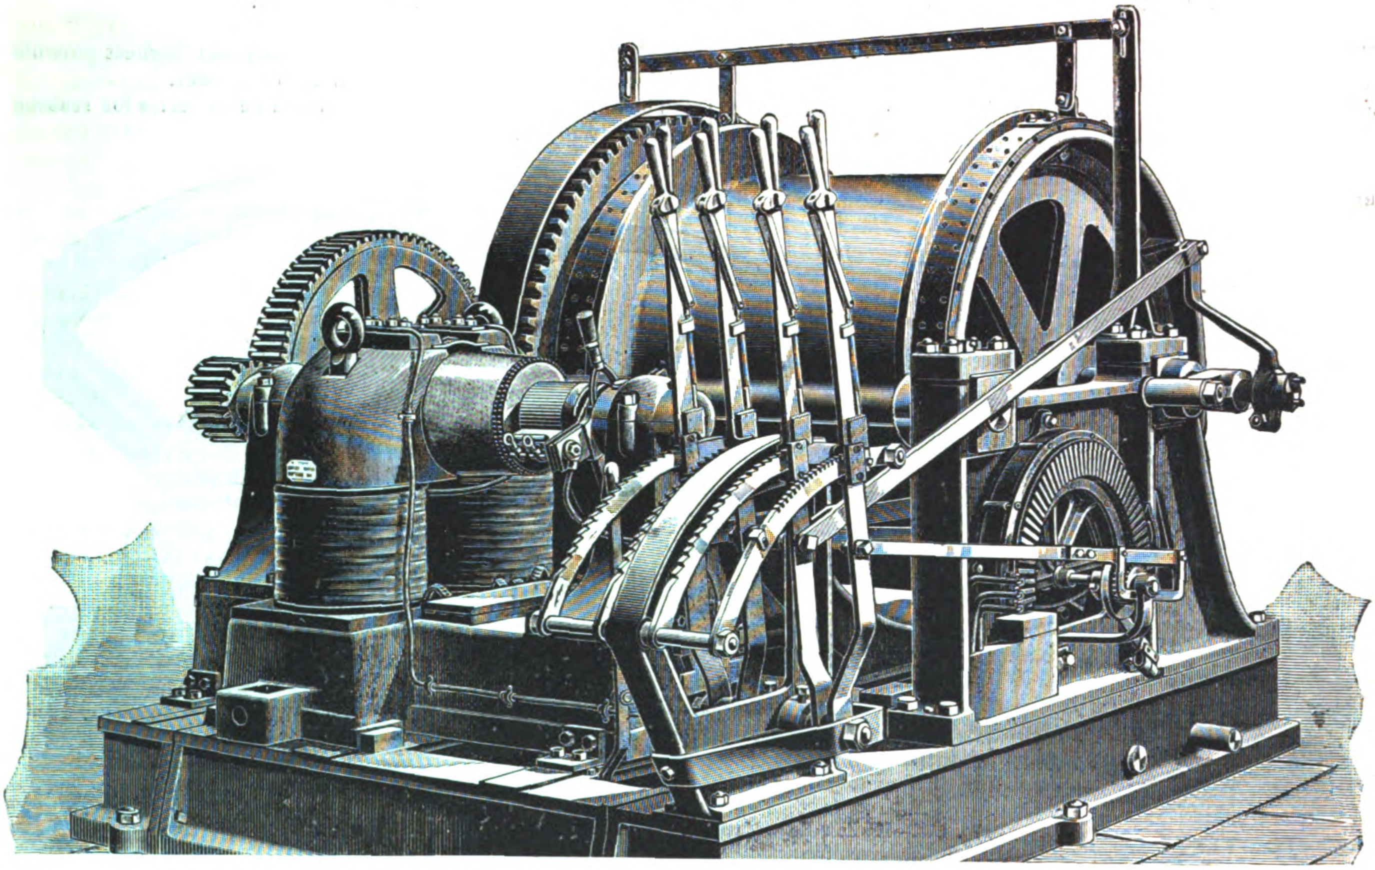

Fig. 114.—Thomson-Houston Single Rope Haulage or Winding Engine.

Digitized by Google

augmented at times by tubs leaving the rails. There is not much fear of overloading during busy periods, because an increase of torque will slow the motor and hence decrease the actual power; but since the current will be temporarily increased, a margin for the heating effect in the windings must be provided.

If, however, the system of haulage be a main-and-tail one, as indicated in Fig. 113, where the motor has to be constantly stopped, and to deal with a continually varying load, good speed regulation and perfect control of the motor become of more importance than efficiency. In this case a specially designed cumulative compound motor may be used with a switch and starting resistance designed to keep the shunt coils always in circuit during work time, and to introduce a variable resistance in series with the armature and series-windings. Reversals of motion should be made by means of friction clutches and gearing, *not* by the motor, as this would introduce complications which are better avoided in pit work. The maximum torque in this case is generally that at starting, but not necessarily, as the load may start on the level, and afterwards have to climb a steep grade.

The best arrangement for working main-and-tail rope systems is to run the motor continuously, and to give forward or backward motion to the rope drums through friction clutches mounted on an intermediate shaft. If the motor be designed in accordance with the above suggestion, no trouble will be experienced.

The preceding remarks are also generally applicable to single-rope haulage, although in some cases, where the load is small and the pressure low, a series motor with a large starting resistance may prove satisfactory. A suitable arrangement for single rope haulage or winding is shown in Fig. 114.

For main winding gear, which is worked practically continuously during a shift, the author prefers a cumulative compound motor having a large regulating resistance, the motor running in one direction only, and the reversals being made through friction clutches as already described for main-and-tail hauling. But if the winding be used only occasionally, as frequently occurs with staple-pits, then a series motor with a large regulating resistance is preferable. The time occupied in raising the load is so short that the question of speed regulation does not enter into the problem. What is required is a large power at starting, gradually yet quickly applied, and perfect control over the cage at all parts of the run, but specially when stopping. It is also necessary to be able to raise or lower the cage a few inches. For such work the author has found series motors to give excellent results. He finds it convenient to couple the brake lever to the friction clutch so that when the brake is applied the circuit is opened, and the motor is then ready for raising or lowering as required.

(*To be continued.*)

ENTROPY.

It has sometimes been stated that the truths about entropy and its relation to heat and energy are mere algebraic abstractions which cannot be illustrated or exemplified by any physical facts. That this view of the case is erroneous everyone who has really grasped the true significance of entropy will readily admit. Not only has entropy abundant illustration in the phenomena of hydraulics and electricity, but we may depart entirely from the region of physics, and find an analogue in the principles of value and finance. Let a man have a quantity of some goods or other, by the exchange or sale of which he can derive commercial benefit. The gross value of these goods may be called the financial energy of the man and corresponds to his wealth. This amount of financial energy is the product of two factors. The first factor is the intensity of value, or "exchange rate," or what we may call the financial potential of the goods; this corresponds to the absolute temperature of a hot body. We may fix the absolute zero of financial temperature, or potential, by taking a standard substance, *e.g.*, gold, and considering the financial temperature of this standard as a datum. The second factor is the entropy of the goods, or what we may call the financial entropy of the valued material. The entropy will, of course, be directly proportional to the quantity of goods. Now, just as there are two definite processes by which a hot body may gain or lose heat energy—the adiabatic and the isothermal processes—so there are two corresponding definite processes by which a man may grow richer or poorer. A man—the financial working substance—grows richer or poorer adiabatically, as it were, when his goods do not alter in quantity, but improve or fall in their intensity of value—*i.e.*, their financial temperature. A cute business man buys his goods at a low temperature, and floats them up, adiabatically, to a high temperature, when he discharges the improved value into the store of—not heat—wealth, *i.e.*, the bank. He is a reversed Carnot engine, speaking financially. Now the other fellow, the bad man of business, works himself the other way round. He takes in entropy at a high temperature, and drops down the market to a point where he has to unload at a lower price, *i.e.*, financially his goods have become cooler. Probably he, himself, is in a fever, but that is another story. All the time, in either of these cases, that the goods are moving up or down the market —*i.e.*, the thermometer—their quantity, or entropy, does not alter in the least.

The second way in which a man may become richer or poorer may be called the isothermal method. This consists in varying the quantity of the goods without altering their intrinsic value per unit of quantity. The total entropy will then, of course, increase if the goods are increased and decrease if the goods are decreased. When a man drops a sovereign through a hole in his pocket he becomes poorer in the isothermal way; and when he picks up a like coin he becomes richer along the same curve, as it were. The value in gold—the financial temperature of the stuff—does not alter one bit during either of these processes. Penny-in-the-slot cigarette machines afford another example, when the penny passes isothermally to the owners, the cigarette remaining in the machine. The temper, if not the temperature of the disappointed smoker is, however, likely to rise. Another instance of isothermally becoming richer is the case of a farmer who sows, say, a peck of grain at a certain price per peck, and sells a crop of a hundred pecks at the same price per peck. Again, the acquisition of wealth by bequest from a dead person is an instance of an isothermal rise in financial energy; and this case is more especially like the flow of steam into an engine through a leaky pipe, the leak being called "death duties."

One point more and our analogy must be concluded. There is often a difficulty in understanding the statement that entropy tends to a maximum. We may illustrate this financially in the following manner. Suppose wealth, like physical energy, to be a conservative system; *i.e.*, suppose the magnitude of wealth to be a fixed quantity. Consider any given quantity of wealth, the magnitude of this is the product of the two above-named factors. Now, in the physical universe, the temperature tends to fall to a minimum. In the financial universe, if the given quantity of wealth falls in its intrinsic value per unit of goods, its fixed amount can only be maintained by an increase in the quantity of goods. Thus, the lower the intrinsic value of any thing, the more of it will be required to make up any given amount of wealth. The financial temperature of copper is lower than that of gold; therefore, if a given amount of wealth is to be stored in copper, a greater quantity of the material will be required than if stored in gold, *i.e.*, there will be a greater entropy necessary in the former than in the latter case. If we could conceive of a substance being at the absolute zero of value, we should require an infinite amount of it to obtain any wealth at all. In the same way, heat entering or leaving a substance at the absolute zero of temperature requires an infinite change in the entropy of the substance.

There are many other points of similarity between the laws of entropy-temperature and the laws of value and wealth; but these we must leave to the imaginative faculties of our readers to evolve for themselves. The little we have already given may suffice to indicate the nature of the analogy; and our purpose will have been attained if we have in any way contributed to the enlightenment of an unmathematical mind upon a somewhat difficult branch of physics.

AN ELECTRIC HEATER.

Mr. H. Ward Leonard has taken out a patent for an electric heater which is likely to mark an advance in that line. It is very important for the operation of such tools as electric soldering-irons, flat-irons, embossing-irons, and many other similar tools, that the heat developed in the resistance shall be conducted to the working surface as rapidly as possible, and with the least amount of waste. The necessity of a resistance which would stand a very high temperature has been such that platinum wire is often used in the construction of such tools, the expense of which is, of course, extremely high, but even this has failed under such conditions.

Mr. Leonard has many modifications of the general principles of his invention, but the description of one modification will give a general idea of the invention. The resistance, which is a metal wire, is thinly coated with some form of fireproof insulation, which hermetically seals the conductor from the air, such as enamel or glass. The wall of insulation around the conductor is quite thin. The conductor so insulated is placed in a mould, and a suitable metal is cast about the insulated resistance so as to completely embed it in the cast metal. This surrounding body of metal as it cools subjects the insulated conductor to strong pressure, insuring perfect mechanical contact throughout. The surrounding metal also hermetically seals the resistance from any possible contact with the air, and from all chemical action. While the insulation surrounding the conductor is of comparatively poor quality as a conductor of heat, the wall of this insulation is so thin that it affords the least possible resistance to the flux of heat from the heated resistance of the surrounding metal body; consequently, the temperature of the heated resistance and the temperature at the surface of use will be as nearly the same as possible, and the resistance is, therefore, not subjected to a temperature appreciably higher than that of the surface of use. It is possible, it is said, to operate tools heated by the Leonard system at a bright red heat without any destructive effect whatever, and this possibility opens up a very wide field for the application of electricity to various tools used in the various arts and industries which have heretofore necessarily been heated by gas, charcoal stoves, &c. The Carpenter Enamel Rheostat Company, of which Mr. Leonard is President, will manufacture apparatus under this patent.

TELEGRAPHIC COMMUNICATION BY INDUCTION BY MEANS OF COILS.*

BY CHARLES A. STEVENSON, B.SC., F.R.S.E., M.INST.C.E.

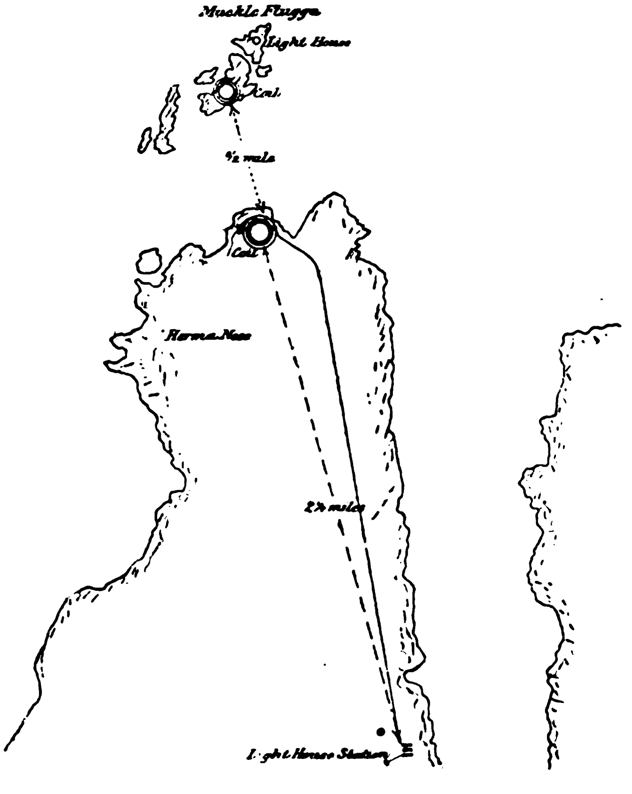
In 1892 I suggested that communication could be established between ship and ship by means of coils,† and as a trial of the system on a large scale has recently been made with the view of establishing communication between North Unst lighthouse, situated on Muckle Flugga, and the mainland (*see* Figure), thence to the lighthouse station at Burrafiord, a distance of two miles, a record of the trials may be of interest to the Society.

A number of experiments were made in the laboratory to discover the laws of the action of coils on each other, with a view of calculating the number of wires, the diameter of coils, the number of amperes, and the resistance of the coils that would be necessary to communicate with Muckle Flugga, and after a careful investigation, it was evident that the gap of 800 yards could, with certainty, be bridged by a current of one ampere with coils of nine turns of No. 8 iron wire in each coil, the coils being 200 yards in diameter.

Two coils, about 850 yards centre to centre, were erected at Murrayfield, one coil being on the farm of Damhead, and the other on the farm of Saughton, and as nearly as was possible on a similar scale and the coils of similar shape as was wished at Muckle Flugga. On erecting the coils, communication was found impossible, owing to the induction currents from the lines from Edinburgh to Glasgow, the messages in these lines being quite easily read, although the coils were entirely insulated and were not earthed. The phonopore which the North British Railway Company have on their lines kept up a nearly constant musical sound, which entirely prevented observations. On getting the phonopore stopped, it was found that 100 dry cells, with 1·2 ohms resistance each and 1·4 volts, gave good results, the observations being read with great ease in the secondary by means of two telephones. The cells were reduced in number down to 15, and messages could still easily be sent, the resistance of the primary being 24 ohms and the secondary no less than 260 ohms. If the circuit had been of good iron, with soldered joints, and well earthed, the resistance should have been only 60 ohms.

The calculation of the diameter necessary to hear a given distance is simple, from the fact that the hearing distance is proportional to the $\sqrt{\ }$ of the diameter of one of the coils, or directly as the diameter of the two coils, so that, with any given number of amperes and number of turns to hear double the distance requires double the diameter of coils, or double the number of turns, and so on. But this is within certain limits, for when the coils are close to one another the law does not hold.

The author then briefly described some experiments made to test the relative merits of the "parallel wire" systems and "coil" systems. With regard to the question whether or not the parallel wire system is actuated by induction or conduction, it will, he says, depend how the ends are earthed, or, in short, what is the distance bridged in comparison to the breadth of base, which predominates. Where the wires are long in comparison with the distance bridged, conduction will be the main working factor, but when the base is small, and the distance bridged is large in comparison, induction will be the main factor, and the number of turns then increases the effect.



The primary coil was insulated in the Murrayfield trials, as at Muckle Flugga it must be so, the impracticability of making and maintaining the sea connections necessitating this, and the secondary was earthed, as is most convenient at Muckle Flugga. When the secondary was also made a complete insulated metallic circuit, there seemed to be little difference in the result.

There is one other point to which reference must be made. Mr. Preece has been repeating the experiments brought before this Society on January 30, 1893, and he found, if rightly reported, that when the hearing wire was floating he got results, but when it was allowed to descend that no observations could be got; he attributes this to reflection from the surface of the water; this, however, is unlikely, as the reason that no sounds were then heard was that the major part of the wire lay on an equipotential line. Electro-magnetic waves enter or leave salt water practically unimpaired. On trial, it was found, as stated in my paper read before this Society in January, 1893, that there was no *practical* difference in air or salt water to the propagation of electro-magnetic waves, in or out the distance to which waves went—*i.e.*, the distance to which the currents could be heard being immaterial whether the detector was sunk or in air.

It has been attempted to be shown that the coil system is not only theoretically but practically the best. Meantime, my brother has recommended the Commissioners of Northern Lighthouses to erect the coil system at Muckle Flugga, and the Commissioners have

* Abstract of a Paper read before the Royal Society of Edinburgh, March 19, 1894.

† *Engineer*, Vol. LXXIII., p. 292.

Digitized by Google

approved, and I hope that we may soon hear of this novel system of communication being erected at the most northern point of the British Isles, where the laying-down and after-maintenance of a submarine cable is practically impossible. This system is also applicable to our warships, to assist in their manœuvring, by the establishment of instantaneous communication unaffected by wind or weather.

The application of the coil system to communication with light-vessels is obvious, namely, to moor the vessel in the ordinary way, and lay out from the shore a cable, and circle the area over which the lightship moorings will permit her to travel by a coil of the cable the required diameter, which will be twice the length of her chain cable. On board the vessel there will be another coil of a number of turns of thick wire. Ten cells on the lightship and ten on the shore will be sufficient for the installation. The system erected at Kentish Knock and other light-vessels is expensive in moorings, and is liable to derangement, and requires special appliances; whereas, by the coil system there can be no derangement, and the vessel can be moored in the ordinary way. A call arrangement and telephones complete the installation.

COST OF ELECTRICAL ENERGY.

(*Concluded from page 357.*)

Mr. CROMPTON (in reply): The length of the discussion, the number of speakers, and the number of subjects touched upon, make it necessary for me to group these subjects, instead of replying to each speaker individually.

Several gentlemen ask why I selected works having such a large output as 5,000,000 units per annum as a basis for my ideal figures; and Mr. Hammond rather scared us when he said that the gross income of very few gas works would reach the sum of £62,000 a year, which is the gross income corresponding to 5,000,000 units at 3d. He, however, has now found out that he is mistaken in this, and that the income of a very large number of gas undertakings greatly exceeds this figure. At any rate, I have no doubt that, in London, the works of the Westminster Company, the Metropolitan Company, and probably the City of London Company, will reach this rate of output within two or three years; and that even the smaller companies with which I am personally connected will approach it so nearly that my ideal costs, so far as they depend on scale of output, may be also closely approached.

As to the capital cost of works capable of dealing with this output, I can assure General Webber, and Messrs. Geipel, Raworth, Hammond, and others, that I went very carefully into the existing figures before I satisfied myself that a works capital cost of 2s. per unit sold was a correct figure to adopt. I arrived at this figure in the manner which Gen. Webber himself would approve of—*i.e.*, I took the actual figures from the companies with which I am in close connection, and from these I prepared my calculations. I did not use the antiquated plan of calculating by lamps connected to the system, which for many reasons, is no longer a useful guide. The two quantities or factors required are those which enable us to calculate the load-factor for any district, and can be easily ascertained from existing experience of works supplying electricity to a similar district; these two quantities are the maximum in kilowatts of load observed during the year, and the output in units sold per annum. The relation which this latter quantity bears to the observed maxima in various works enables us to say that the maximum rate of output, and hence the size of the plant, may be obtained by dividing the output per annum in units by a figure which is a number of hours, and which varies from 900 hours, or a load-factor of 10·3, in the case of some provincial towns, up to 1,300 hours, or a load-factor of 14·8, in my Kensington district, and to even higher figures in other parts of London. The quotient thus obtained is the maximum load in kilowatts. For the purposes of my Paper I took the very safe figure of 1,000 hours, corresponding to a load-factor of 11·4, so that for an output of 5,000,000 units I require 5,000 kilowatt plant. In these works the generating plant must necessarily have from 20 to 25 per cent. of machinery in reserve, although the distributing plant need only be of the exact capacity, so that the 5,000-kilowatt load may be dealt with without undue fall of pressure in the mains.

My capital expediture of £500,000 is therefore a very safe estimate—in fact, I believe it to be an outside figure; but, much as I should like to enlarge on this point, space does not permit me to labour it. Messrs. Geipel and Hammond, and even General Webber himself, have, however, put figures before you showing that, in their opinion, it can be done at from £75 down to as low a figure as £60 per kilowatt; whereas it will be seen that I have adopted £100; and, as I am in a responsible position in regard to certain works designed by me, I know with reasonable certainty that the present plant in its completed state will, when working at present load-factors, not cost more than this sum—in fact, I hope it will cost considerably less.

The next point raised in the discussion was whether I am correct in asserting that the management and profit items in working costs are outside the province of us engineers. Messrs. Geipel and Mr. Hunter, the engineer of the Newcastle and District Company, in his communicated remarks, have pointed out that these two items cannot be left out when considering the whole cost of production, and I agree with them; but why do they speak as if I had left them out? I think that the words in my Paper, paragraph 2, p. 397, sufficiently explain why I did not take up unnecessary time on this point; in fact, Gen. Webber criticises me rather sharply for the little that I did say.

Coming now to my estimate of ideal costs, three speakers—Gen. Webber, Messrs. Geipel and de Segundo—criticise me rather severely. Eight other speakers—among them Messrs. Raworth, Robinson, Kennedy and Holmes—have, however, criticised them favourably, and taken these costs in the manner intended by me, viz., that my ideal costs were intentionally pitched high, and difficult of attainment. The fact that several of those who contributed to the discussion have already been able to show figures in some measure approaching to these ideals is a cheering one, and is the best answer to my first-named critics.

Mr. de Segundo has dealt with my ideal figures at length; but it will be more convenient to deal with his remarks, and those of others, on the subject of ideal boiler and engine efficiencies when dealing with these two matters further on, but Messrs. Hammond and Holmes offer serious matter for consideration on the depreciation question. On this question of depreciation opinions differ very widely, and I can only give my own as one among many; but I venture also to give my reasons for my opinion, which is sometimes said to be a dangerous course. I believe that in working costs there should be no allowance whatever for depreciation of plant. Of course, I am not dealing with the case of plant owned by local authorities, who by the regulations of the Local Government Office are obliged to set aside certain annual sums as a sinking fund, so that at the end of a fixed period the whole capital that has been borrowed for the works will be paid off; but in the case of supply companies holding a concession for a limited term of years, I believe that the true course is to spend annually and charge against revenue such a sum as is sufficient to maintain the plant in perfect working order. During early years the annual sum required will be smaller than at a later date, when the plant has become worn; so that it is advisable during these early years to set aside a sum in excess of the sum actually spent on repairs, in order to equalise these maintenance costs from year to year; but if this has been properly done, at the end of the concession there should be no balance left over one way or the other—that is to say, the plant should be in perfect working order, and there should be no depreciation fund existing.

We are indebted to Mr. Hammond for inventing a highly useful word—"antiquation." This is an entirely different matter from depreciation, and I think no provision should be made for it. I do not think that other public companies, such as railway companies, water companies, or gas companies, ever have thought of providing an antiquation fund. What is the use of such a fund? I presume, to enable us in the future to purchase, and use for purposes of reducing working costs, any future inventions which we are now ignorant of; but surely, before the adoption of any such future improvement would be decided on, it must be shown to pay—that is to say, not only to reduce the working costs below their then level, but to such an extent as to pay the interest on the sum sunk on the improvement; and if it is of this nature there could be no difficulty in raising fresh capital to introduce the improvement. Why should present ratepayers, or present shareholders, pay for improvements destined to benefit those who follow them?

Further than this, I cannot help feeling that this desire for an antiquation fund is due to an uneasy feeling in the minds of some engineers that their present plant is not quite what it should be—that it is already antiquated, and that they had better, as soon as possible, begin to set about replacing it by something better. I am happy to say that this is a feeling which has not oppressed me. When we already have such good generating plant as we have at present, and when our distribution losses are only 10 per cent. it is not easy for us to see what we are likely to gain from further improvements. Such improvements as are continually introduced into the best class of plant concern only the cheapening of the manufacture of that plant, and the future purchasers of it—that is to say, the plant in the future will be probably very little better than the present, but it may be very much cheaper; this, however, is no reason for antiquating present good plant in order to purchase cheaper plant of the same type and efficiency. It is for these reasons that I have left out depreciation and antiquation from my ideal costs, and only put in a sum of 0·4d. per unit, which I think will, on the scale proposed, be sufficient to keep the plant in perfect working order.

Value of Fuels.

As I had expected—I may say hoped—this important subject has been well discussed by those who are most competent to offer opinions on it. The discussion has only confirmed my views that the fortunate users of Welsh coal ought to congratulate themselves as having escaped the worries and uncertainties attending the use of the bituminous and other coals which contain so much of their thermal efficiency in the form of hydrogen. I see that Mr. Raworth and Prof. Kennedy support me strongly on this point; and although Prof. Unwin quotes tests to contradict my views, he only quotes test runs which, as I have shown by my Chelmsford experience, only lead to erroneous conclusions, whereas those who support me do so from their knowledge of the continuous figures of the many works with which they are connected; but I think that the words Mr. Hunter, of the Newcastle and District Company, makes use of in his communication are most significative. Mr. Hunter, in wishing to reduce the figure which I give in Table VI. of 310 units per watt-hour sold, says that the calorific value of the Newcastle slack used by him is only one-half that of Welsh coal—that is to say, 7,250 British thermal units—and on this basis he corrects or reduces my figure of 310 to 204 British thermal units. Now I thoroughly sympathise with Mr. Hunter in this. I know that, with ordinary boilers and ordinary care in stoking, the slack that he uses will only evaporate about half the water that he could evaporate with Welsh coal; but from my own experience at Chelmsford, where I have been using precisely similar coal to that he uses, I am convinced that if he has a calorimeter test made of his slack he will find that I under-estimated its value, and that it contains from 12,500 up to 14,000 British thermal units, a large proportion of these being in the hydrogen form, and thus extremely difficult to utilise; and he will also find out the

Digitized by Google

truth of Mr. Halpin's remarks on the extent that this small slack deteriorates by exposure to the air. I do not think that Prof. Unwin has any right to say that the use of Welsh coal is one of the factors of my formula. I pointed out, and I now re-affirm, that we in practice find out that it is easier to get a good result with Welsh than with the other coals. I never said that it was impossible, but only that it was difficult, to get good results with the other coals.

We now come to the vexed question of flued *versus* tubular boilers. Some speakers will have it that it is Lancashire *versus* Babcock, but it is not so. Here my friendly critics are more numerous than the adverse ones. I fully expected to call a storm down on my head when I raised this question; but I raised it advisedly, after carefully watching and comparing the results in works using the two types, and after many and careful tests had been made by me personally. It is unnecessary for me to refer individually to the advocates of the Lancashire boiler. Their one cry is that in the past Lancashire boilers have given good results as steam raisers, and that on tests they have shown practically as good results as other types; but no advocate of these Lancashire boilers has attempted to explain why in the works E, N, O, and J the evaporation is so low. I have given my explanation. I have shown that, whereas at works J the results on test runs were 9lb. of water evaporated per pound of fuel, the year's accounts show that only 5·21b. were evaporated. I have traced this difference in results to the falling-off in evaporating efficiency which always occurs when the Lancashire or Cornish type of boiler is irregularly fired, as it always must be when used in electrical works, and to the further difficulties which arise with this type of boiler if the coal varies even slightly in composition. I have shown that these differences can be reduced by the use of economisers—which virtually are a tubular addition or extension to the Lancashire boiler, making it partly a tubular boiler—and that these differences do not exist to the same extent when tubular boilers are used, whether of the Babcock type or of the internally fired type, such as the "Economic" or marine; and if all that has been said in the discussion is carefully read, it will be seen that no one has seriously controverted this view.

I object strongly to the statements made in the course of the discussion, and in the leading articles in the technical journals, that I hold a brief for the Babcock and Wilcox type of boiler. This is a cheap form of criticism, which happens to be exceedingly wide of the mark. Three years ago, when discussing the best type of boiler for electrical works, I thought that the internally fired boilers ought to beat the Babcock, or any externally fired type, on account of reduced losses during periods of banking the fires; therefore it was only simple justice on my part that I should state the results of my more recent experience during the last three years, when I find that, after fair trials of all types, the Babcock, which is an externally fired boiler, still holds its own.

Mr. Rosenthal has very fairly defended this type of boiler from the attacks made upon it during the discussion. So many well-qualified speakers have admitted that it is free from the defects of producing wet steam, and that it gives good evaporative results in supply works, that the only important point necessary to notice is how this class of boiler stands in regard to forced firing. I believe in this respect it is the best of all the boilers I have tried. I have, for the reasons given by Mr. Rosenthal, and which I consider to be very fair ones, never considered the question of heating surface in regard to this boiler, or, in fact, of any other boiler. The practical question which we engineers have to consider is not the one of heating surface, but of the space occupied, and of the evaporative efficiency of a boiler which at certain times must give a certain output. When tested by this standard, I find that the method of preparing a figure of merit advocated by Mr. Halpin is not correct. His method is to obtain from the three factors of evaporative efficiency, pounds of water evaporated per square foot of heating surface, and cost of heating surface, a figure which he shows to be from two to two and a-half times greater in the Lancashire boiler than in the Babcock. In reply to this, I have prepared during the last six years a very large number of estimates of boiler plant, and have most carefully considered the cost per 1,000 gallons per hour which can be evaporated at periods of maximum load; that is to say, when the fires of both types of boiler are being forced. I find that under such conditions, when all items of cost, exclusive of economisers, are added in in both cases, at this size the prices of the two types of boiler are practically identical; but that the evaporative efficiency when Welsh coals are used is, in practice, at least 25 per cent. in favour of the Babcock; and when we add to this that the Babcock boiler occupies just about half the floor space, and that it is far easier to deal with, there is little wonder that those who have had experience of both types exhibit the preference that I do. Still, as I have explained above, the question is not between Lancashire and Babcock, but between flued boilers generally and tubular or tubulous boilers; and I do not offer any strong opinion on the comparative merits of these two last-named types. I have had as good results from one type as the other, and no doubt the choice between the two will be determined in each case by special circumstances. How local circumstances affect design is very well shown by the remarks of Messrs. Burnett and Peache, on behalf of Messrs. Paxman. Both gentlemen are makers of what I have called the semi-marine type, but which Messrs. Paxman call the "Economic," and Mr. Burnett the "Dry-Back" type. Mr. Paxman makes the boiler longer, and smaller in diameter, which suits the Welsh coals we find in the South of England; whereas Mr. Burnett, having to deal with Scotch coals, prefers a large-diameter short boiler; and both types are giving excellent results.

Mr. de Segundo has been at great pains to show that my ideal boiler efficiency is an impossible one; but his method of first deducting the principal source of boiler loss—*i.e.*, the heat units which go up the chimney—before he calculates the boiler efficiency, is very unusual, and differs from the system usually adopted. Of course, under such circumstances, when the one large source of loss has been eliminated, the boiler efficiency can show exceedingly high.

The figure of a possible 12lb. and a 10lb. working evaporation adopted by me is, I am convinced, not an impossible one, as so many authenticated tests show; among these, I will point not only to the trials made by Prof. Robinson at St. Pancras with the Babcock and Wilcox, Prof. Kennedy at Eccleston-place with an "Economic," and Prof. Kennedy with a Thornycroft boiler, which in each case show an evaporation in excess of what I require, but to the well-authenticated trials made by the Royal Agricultural Society of England at Cardiff and Newcastle, and to the 60 extended trials quoted by Mr. Halpin with Lancashire boilers.

I note Mr. McLaren's preference for locomotive boilers, which is not to be wondered at, as he has obtained such high results in competitive trials when these boilers are used; but Mr. Halpin and Mr. Burnett have admitted that the type of locomotive boiler usually now built is a very awkward one to deal with in central stations; and, moreover, I think Mr. McLaren would not find that a locomotive boiler comes out well when required to be of the large sizes we generally require in supply works.

Mr. Geipel seems to think that the use of boiler fluid should be discouraged, and that it is an unworkmanlike method of dealing with the question of deposit; that where water is bad, special purifying plant should be used. Here, again, it is a question of special circumstances. There is no doubt that where the water is beyond a certain degree of hardness, purifying plant must be used; but there are many cases, such as that of the Thames water supplied by several of the London companies, where the hardness is not sufficient to warrant the use of purifying plant, and where the use of small quantities of boiler fluid at the proper time will result in keeping the boiler absolutely free from any deposit whatever. It is not a question of allowing the deposit to form, but of keeping the boiler absolutely clean; and this can be done, and is done in practice in the best works.

On the question of oil fuel Mr. Henwood is evidently an enthusiast, and I should be very pleased to see the rosy figures named by him realised in practice; I for one shall be well content if we get a much lower duty from the oil than that given by him. The great obstacle to the large introduction of oil fuel is the present price of the oil; and until this is considerably reduced, all our experiments must be in the nature of adopting oil for periods of forcing only. So far as experiments have gone, I believe that with the Babcock type the output of boilers under conditions of forcing will be nearly doubled; and I am glad to say that even under these circumstances this type of boiler still produces dry steam.

It is disappointing to see that the question of economisers has been so lightly touched on in the discussion. I had hoped to hear the experience of gentlemen who are large users of this class of plant, more particularly as to the cost of the upkeep of this extra item of plant. What we electrical engineers want to know is the cost of maintenance of economisers exposed to the very high pressure now prevalent.

On the subject of high *versus* low-speed engines, it is very evident from the discussion that opinions have advanced very rapidly in the same direction as my own; and that, whereas, as I have stated, in my Paper six years ago I was almost alone in advocating their use, now the great majority of speakers either admit that they are the most economical and convenient form to use in supply works, or they have arrived at the half-way stage of admitting that direct driving is of great importance.

I challenge the correctness of the remarks of Mr. Wilmshurst when he says that in the most modern stations rope driving, alternators, and Lancashire boilers have been, and are to be, used in overwhelming numbers. On the contrary, there has been a distinct tendency in all recent specifications to do away with rope driving. A notable conversion to direct driving has been Mr. Raworth, and the only two speakers who still speak lovingly of the long-stroke horizontal engine are Prof. Unwin and Mr. Gray. I think both these gentlemen have been influenced by their surroundings—that is to say, by the very beautiful steam plant of this type which has been manufactured of late years on the Continent. The eye of a mechanical engineer is taken by the design, workmanship and high efficiency shown by the engines of Van der Kirkhove, Carels, and others; but even among these famed makers a feeling in favour of high-speed engines for electric supply works has already set in, Messrs. Van der Kirkhove being the first on the Continent to take up the manufacture of the Willans type of engines, and are now advocating its use for such works.

I have already taken objection to Prof. Unwin having fathered on me a formula for the design of supply works plant. It may be true that the figures which I have collected for purposes of comparison show that certain supply works containing that class of plant have done better than others, but nothing could be further from my thoughts than to suggest a hard-and-fast formula to suit all cases. Prof. Unwin says that in my Paper I convey the idea that high speed of rotation is the one and only method available for reducing cylinder condensation, and that I have neglected the other methods—namely, use of jackets, superheating, and expansion by stages. With great deference to Prof. Unwin's high-standing and special knowledge on this subject, I must point out to him that here he is wrong—that high speed of rotation is not a method alternative to these other methods, but it can be superadded to all or any one of them; and that, in addition, high speed of rotation offers us great advantages by reducing the size, space occupied, weight, and hence the cost, of both the engines and dynamos, while at the same time it increases their economic efficiency; so that from all points of view it is the most satisfactory modification of design which the special requirements of electric lighting supply works have forced upon us.

As to my ideal figures of steam consumption, I have already said that these were intentionally pitched high, and difficult of attainment; but Mr. de Segundo's figures are evidently too much the other way. It is no use to compare them with mine, as he deals with non-condensing, whereas mine refer to condensing engines; so that his best possible figure of 4lb. of coal per unit sold with a non-condensing engine cannot be compared with

Digitized by Google

my 2½lb. with a condensing engine; but even with non-condensing engines Mr. Barley, at Knightsbridge, and Prof. Kennedy in more than one of his stations, have already reached a point below 5lb. in some of the winter months, and at Knightsbridge 3½lb. has been reached during test runs of considerable duration.

I have now to deal with the lengthy criticisms which have been made on Table VI. Several small errors have been pointed out, which I have duly corrected. These lie chiefly in the efficiency of distribution, and consequently alter the thermal units used per unit generated. General Webber is the only speaker who has impugned its accuracy as a whole, on the grounds that he is able to state from personal knowledge that the Chelsea Company, of which he is a Director, refused to supply the information requisite to correct and supplement the published figures. It is true that this refusal caused an error in the distribution efficiency of the Chelsea Company, which I have already admitted, but it was the only refusal that I received. It did not cause me to draw any false conclusions, as I did not use the Chelsea figures in my averages, and I have based no arguments on them. It is, however, evident, as the order of merit in this table is based on column 4—that is, the B.T.U. per watt-hour sold—that the Chelsea Company, costing 1·11d., and using 142 B.T.U. occupies a figure of merit somewhat higher than that of the Charing-cross and below that of the St. James and Pall Mall Company, which is a high position, on which Mr. King and his staff are to be congratulated.

I hope Mr. McLean does not think I intended to throw doubt on the Oxford figures. On the contrary, when I said that they appeared almost too good to be true, I certainly intended to congratulate him on the splendid results obtained in such a short time after the starting of this station. I indeed consider them very encouraging to those who, like myself, think that the Oxford system is in many respects a more satisfactory method of dealing with the supply of scattered districts than the ordinary converted alternating system. Again, I thoroughly agree with this speaker as to the advantages of keeping records in very full detail; but he quite misunderstood my remarks on the distribution efficiency obtained at Chelmsford. I pointed out that, although the efficiency shown was high, it was not fair for us to take credit for it when compared with companies who supply throughout the 24 hours, as we gain considerably in efficiency from switching off the energy during a part of the daylight hours.

I am glad to find that Mr. Dykes has been able to so satisfactorily explain the Preston figures. At the time I worked out these figures for my Table I felt sure that some explanation would be forthcoming. His explanation shows clearly that a direct system, if used without accumulators, loses many of its economical advantages.

I value Mr. Holmes's remarks very highly indeed. He has had the longest experience of central station supply of any one of us, and has been so uniformly successful in his results that I am glad that his own calculations corroborate so closely my own ideal figures. He is, no doubt, right in attributing his rather heavy coal bill to the peculiar circumstances of last year's working, which, owing to the opening of new stations, led to light loading of his engines; but I still think that he has suffered more than he will admit from the difficulties I have dwelt on in my Paper in efficiently burning slack coal in the Lancashire boilers.

I am afraid I cannot enter at any length on Mr. Wilmshurst's communicated criticism, further than to say that he is mistaken in thinking that Table VI. does not allow us to draw useful comparisons. Take the case of the works D, belonging to the House-to-House Company, on the one side, and compare their costs with those of works K, U, and W. All of these four works supply a residential district of the West End of London, and the conditions as regards compactness of supply are very similar throughout; yet we find that works D use fuel in the proportion of 265 to works K 142, to works U 116, and to works W 84. Surely such great differences (which in these four cases have been taken very accurately indeed) are instructive as to the relative economical value of the systems used; and we may carry the comparison a step further, and point out that this is a case where the smaller first cost of the works D, on account of the reduced cost of their mains, ought to have led them to compare favourably from the point of view of dividend-paying with the other three works, whereas the working costs of D have been so high as not to permit of this.

Again, Mr. Wilmshurst's conclusions as to Lancashire boilers are in direct contradiction of the data obtainable from Tables III. and VI.; so much so that I cannot think he has ever studied these tables, or attempted to check their accuracy with the recorded figures that he mentions.

I am glad that Prof. Kennedy and other speakers agree with me as to the great importance of studying and tabulating all the sources of loss which he has called "obscure works losses." These, which are common to all systems, have been very generally under-estimated, and hence have been neglected, and have gone on from year to year unchecked, and I hope that my Paper may have done real service in calling attention to their importance.

Coming to the question of losses in distribution, or efficiency of distribution, several speakers have raised this point, and the admirers of the converted alternating system of distribution have been anxious to show that the heavy losses in the first group of Table VI. are exceptional, and that the 82 per cent. efficiency of the City of London Company is what we are to expect in the future from improved converted alternating supply. I hope this may be so, but I am convinced that up to the present time the average distribution efficiency of 66 per cent., shown in Table VI., has been the rule and not the exception; and it remains to be seen whether the attempts to better this figure by employing extra plant and staff to switch transformers in and out of circuit may not result in such an increase in the wages of staff as will counterbalance the gain in efficiency, and this will be especially the case in smaller works serving scattered suburban districts.

I take this opportunity of saying that my own personal conversion to the advantages of alternating distribution, which Messrs. Raworth, Geipel and others so obligingly state has already taken place, must be deferred until I have had better evidence than exists at present as to the possibilities of reducing the working costs of the alternating system. This evidence is not yet forthcoming. The accounts of the two companies at Newcastle, Bournemouth, the House-to-House Company, and even the City of London, are very, very far from showing any such marked improvement as might lead me to be so converted to the converted alternating system, or to ignore the converting losses.

The published accounts of Continental and American supply works, and the reports and conclusions based on these accounts by Continental engineers, show that the majority of these gentlemen hold opinions very similar to my own, but I specially refrained from dragging the question into the discussion. This weighty question can now only be settled by results. Time will show who is right, and it is only wasting the time of this Institution to prolong arguments on a matter like this, which at present can be only one of opinion. It is for this reason that I did not mention in my Paper the question of saving by use of accumulators: although the above-mentioned Continental engineers have quite recently shown that the best results on the Continent, as in England, have been obtained from stations where accumulators are used to a judicious extent. At the same time, I thank Mr. Shoolbred for showing this so clearly in the case of the Bradford works.

Similarly, on the question of maintenance, Mr. Gray has raised a very interesting question, which, however, deserves a Paper entirely to itself—that is, the comparative maintenance cost of different systems of underground conductors. The subject is far too important, and involves such large issues that I only touched upon it as far as to give you our own actual figures for the Kensington and Knightsbridge Company. Mr. Gray, however, quotes figures to show that the continuously insulated cables belonging to the Metropolitan Company cost even less for maintenance than the system of the Kensington and Knightsbridge Company, which is three-quarters of it bare copper in culverts. Although I willingly testify to the extremely high quality of Mr. Gray's cables, yet I do not think that the case he brings forward is a fair one to quote, as the peculiar system adopted by the Metropolitan Company, and which is not likely to be repeated elsewhere, happens to be one which does not expose these continuously insulated conductors to the peculiar source of wear or decay which is generally found. I allude to the point of weakness which occurs at the points where the insulation of the cable is cut into to form a T-joint for the attachment of a customer to the mains. A company such as the Kensington and Knightsbridge Company has at present about 2,000 such T-joints on its system; and we find that, whereas all T-joints of continuously insulated cables require some attention and give some trouble, the same T-joints on bare copper give no trouble whatever; and I should mention that the major portion of the cost of upkeep of the Kensington and Knightsbridge system, as given by me in my Paper, is expended on the maintenance of the T-joints of the continuously-insulated portion of that system.

I hope Mr. Schönheyder will understand that I had no intention of adversely criticising his water meter, which I use so largely in boiler trials, when I said that it is advisable to frequently recalibrate it; the reason is that, although Mr. Schönheyder's meter is one of the best I know, yet, as in order to eliminate errors due to leakage as much as possible the meters used on these trials must be placed at a point on the line of pipes as near the boiler as possible, it has, therefore, to pass hot water through it, so that there is a constant liability of cutting and friction from gritty deposit.

I have to thank Mr. Hammond for his appreciation of the object of my Paper; he has himself done good service in the preparation and publishing of statistics, so that he is in a position to sympathise with anyone who, like myself, has to face the difficulties of getting data together. But I am glad to say that in some works the data are already in such good order that it was an easy task to obtain what I wanted from them; in other cases it was far more difficult; and yet it was quite impossible to take a bird's-eye view of the situation, so that I could get on with the Paper, until I had got the figures for the Tables III., VI., and VII. in a rough form. This task, simple as it now seems, was a work entailing much labour and correspondence. Although a few errors may still exist in these tables, no one has brought forward evidence to show that these exist to a sufficient extent to detract from their value as a means of comparing the present economic efficiency of the electrical works that were in operation at the commencement of this year.

Electrostatic Hysteresis.—Some further experiments by Riccardo Arnò, described in the *Rendiconti dei Lincei*, serve to emphasise the analogy between magnetic and electrostatic hysteresis pointed out by this observer. The relation between the energy W dissipated by a dielectric suspended in a rotating electrostatic field, and the electrostatic induction B is given by the equation $W = K B^e$, where K is a constant, and e differs with the strength of the field. From previous experiments e had been found to be 1·6 for values of B between 0·99 and 2·78 C.G.S. electrostatic units, and 1·9 for values of B between 9·90 and 14·58. As a result of the new series, for very weak fields, e comes out as 1·83, when B ranges from 0·06 to 0·17, and the complete equation for this case is $W = 287{\cdot}240 B^{1{\cdot}830}$. The apparatus was nearly the same as that used in the previous series, the dielectric being a closed hollow cylinder of paraffined cardboard, weighing 2·011gr., and 26mm. long.

The Electrician.

(The Oldest Electrical Journal, 1861—1878.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny

Editorial, Publishing, and Printing Offices:

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months. s. d.	6 months. s. d.	12 months. s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

"THE ELECTRICIAN" *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as an Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Price 12s. 6d., post free 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE By Dr. J. A. FLEMING.

VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.

VOL. II.—THE UTILISATION OF INDUCED CURRENTS Price 12s. 6d. post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free. Also in German, 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free, 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

COMPULSORY PURCHASE OF TRAMWAYS.

The judgment which was delivered in the House of Lords on Monday by the LORD CHANCELLOR and Lords WATSON and SHAND is, as Lord ASHBOURNE, the dissentient judge, remarked, "a decision of deep moment to all the tramway companies in Great Britain, and involves interests of considerable magnitude." To English electrical engineers also this judicial pronouncement is of considerable interest, not only by reason of the somewhat similar purchase clause in the Electric Lighting Act of 1888, but on account of the effect which this final interpretation of the words of the 43rd Section of the Tramways Act of 1870 may have on the future of electric traction in this country.

In August, 1892, the Edinburgh Town Council gave notice to the Edinburgh Street Tramways Company of its intention to purchase that Company's undertaking in the manner laid down by Parliament. Needless to relate, the parties differed as to the sum to be paid. A referee, Mr. HENRY TENNANT, of York, was thereupon appointed by the Board of Trade to fix the price, and in November, 1893, he awarded the Company £213,000, and gave it as his opinion that by the statute the sum to be paid should be such as would pay for the construction and establishment of the line in a condition similar to that in which it was at the moment of sale. The Company, like OLIVER TWIST, asked for more, and in due course the case reached that legal *ultima thule*, the House of Lords, whence comes so much common-sense law, simultaneously with the similar suit of The London Street Tramways Company *v.* The London County Council. In this latter case Sir FREDERICK BRAMWELL was the referee, and he also gave the statute what seems to the lay mind to be its obvious plain English meaning, and, in consequence, failed to satisfy the Company. On Monday the judges of the House of Lords upheld the decision of the two referees and those of the majority of the Courts below.

By the 43rd Section of the Tramways Act it is enacted that a Local Authority may purchase a local tramway undertaking "upon terms of paying the then value (exclusive of

Digitized by Google

any allowance for past or future profits of the undertaking or any compensation for compulsory sale, or other consideration whatever) of the tramway, and all lands, buildings, works, materials, and plant of the promoters suitable to and used by them for the purposes of their undertaking within such district. . . ." How, in face of such a clause, the contention of the companies that the value of the tramway must be ascertained by taking into consideration what rental could be obtained for it, if let, was not laughed out of court long before it reached St. Stephen's is a mystery as great as the meaning of the laboured arguments which counsel brought forward, either in their own or their clients' interest, in support of this extraordinary position. How, also, in face of this clause, the British public ever came to invest something like £11,000,000 in tramways is another mystery upon which that well-versed student of human nature, the company promoter, might no doubt be able to throw some light. Probably they thought that the legislators who formed the purchase clause attached some meaning to the term "value"—a meaning which it ceases to have if the thing valued can neither be worked nor rented, nor sold. The cost of construction has nothing to do with the "then value"; and to have been logical the referees should have appraised the "value" at the selling price of the rails and granite stones. Parliament did not mean that; but if not that, what?

Fortunately for the capital of the small investor, the average yield on that eleven millions does not exceed 5½ per cent., so that in but very few cases is it likely that he bought at a premium, and in most cases he may consequently look forward to the day of municipal purchase with tolerable equanimity. At the same time, notwithstanding the now admitted clearness of the tramway purchase clause and the fortuitously happy circumstance that tramway shares in this country are not usually at a premium, the penny-surprise-packet sort of investment to which the Legislature and the company promoter between them are in these days so frequently treating the public must of necessity send capital seeking for investment elsewhere. The foreign penchant for monopolistic concessions has not hitherto borne strikingly healthy fruit, but at any rate, it is more likely to do so than the new British variant; the former, as a rule, confers a long period monopoly during which a tariff sufficient to pay a normal rate of interest and to build up an adequate capital redemption fund, may be levied; the latter, as a rule, expressly excludes the very idea of monopoly, curtails the grant to the shortest possible period, and as often as not provides for the popular revision of tariff at frequent intervals. So long as capital can be made to flow forth on such terms, the wisdom of municipalisation is, of course, temporarily justified of her children.

Capitalists hoping to finance electric traction undertakings, manufacturers hoping to equip electric lines, and consulting engineers hoping to advise on electric tramway undertakings, will, however, be more concerned about the immediate effect of the House of Lords' decision on their respective prospective profits than about ulterior and general results. As regards existing systems, it seems to us that the conversion of horse-lines into electric-lines, a painfully slow process before this legal decision, is now likely to come to a complete standstill. It is scarcely to be expected that the shareholders of a tramway concern will dream of sinking further capital and adopting electric traction if, a few years hence, their property is to be bought up at a price which would not cover the previous expenditure on equipping the line for the horse system. As to the effect of the negatively famous 43rd clause on tramway construction, now that its purport has been publicly made plain to all whom it may concern, we cannot do better than endorse the weighty words of Mr. Justice MATTHEW in the Divisional Court: "I cannot help thinking that very few tramways would have been constructed under these circumstances, because a shareholder proposing to take shares must satisfy himself that the profits of the undertaking would not only pay him interest upon his investment, but would restore to him wholly or partially, at the end of 21 years, his capital." However, most evils work their own cure, and should the net result of the now publicly-explained 43rd clause be the prevention of all tramway improvements and the cessation of all tramway extensions, it may be safely predicted that one of two things will soon happen: Either the obnoxious clause will be amended, or municipalities generally will be permitted not only to work tramways but also to construct and lease them. Then will arise pæans on the virtues of municipalisation, with its hard cash payments, and of town councillors with their abnormally-developed bumps of business-like shrewdness and public spirit; for it is not given to everyone to perceive, and it is the business of no one in particular to point out, that what is not to the interest of the whole swarm is not to the interest of a single bee.

ON IMPULSIVE CURRENT-RUSHES IN INDUCTIVE CIRCUITS.

BY ALFRED HAY, B.SC. (EDIN.).

(Continued from page 361.)

§ 19. The initial magnetic state of the iron being one of the most important conditions in bringing about a rush of current, it is interesting to investigate how the rush is affected by varying the normal maximum of magnetic induction to which the iron is pushed. We shall consider the case in which the normal maximum does not exceed about 450 C.G.S. ines per sq. cm.

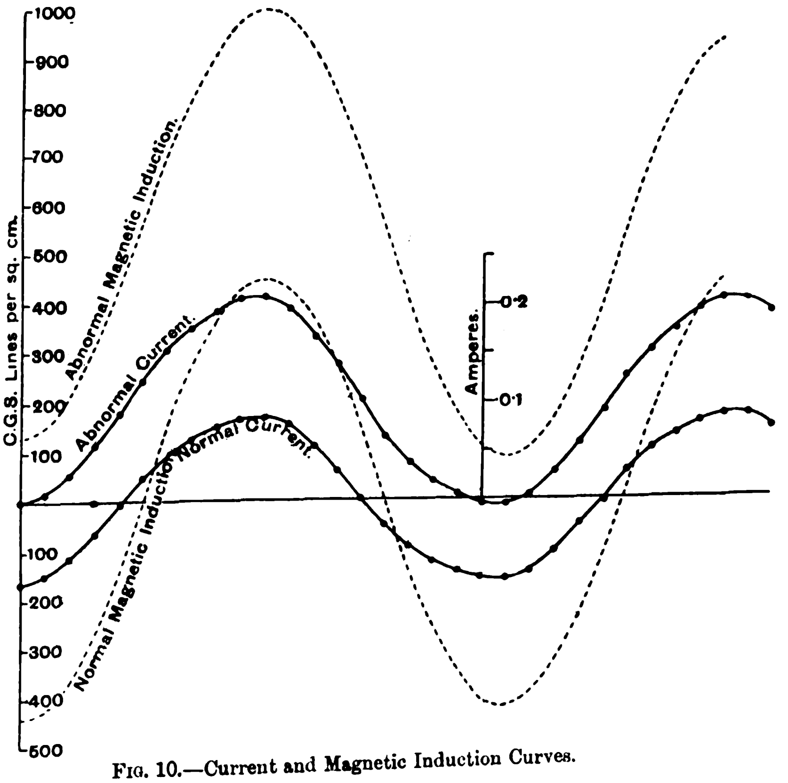

FIG. 10.—Current and Magnetic Induction Curves.

After the readings which are plotted in Fig. 9 had been taken, the connections of the transformer were altered, coil A (§ 13), of 576 turns, being used as the magnetising coil. The resistance of this coil was 1·21 ohms, and the non-inductive resistance connected in series with it was 3·58 ohms, giving a resistance

Digitized by Google

total resistance of about 4·8 ohms. The large amount of non-inductive resistance was necessary on account of the smallness of the magnetising current, whose normal maximum was only about 0·085 ampere. The normal and abnormal curves of current are shown in Fig. 10, as well as the corresponding curves of magnetic induction. The current-rush in this case amounts to $\frac{0\cdot2\text{-}08}{0\cdot085} = 2\cdot45$. The effect of hysteresis being but slight, the deviation of the normal current wave from the pure sine form is comparatively small. The cigar-shaped hysteresis loops corresponding to these curves are shown in Fig. 11, where the thin-line loop is the normal loop, and the dotted one the abnormal. In comparing the loops with those given in Fig. 7, we note the following points of difference: (*a*) In Fig 7 the first descending branch of the abnormal loop crosses the

ings with precisely the same arrangement of circuit as that described in § 19. The results are given in Fig. 12. A comparison of Figs. 10 and 12 at once reveals the fact that the small alternating magnetic force was not sufficient to wipe out the effect of the previous treatment of the iron. The normal hysteresis loop corresponding to Fig. 12 is shown in Fig. 11, being the thick-line loop in that figure. In the case of the loops corresponding to Fig. 10, the origin, which is assumed to be the point of zero induction, in reality corresponds to a certain initial induction. But for the loop corresponding to Fig. 12 it is the true zero of induction. We see that the effect of completely demagnetising the iron to start with is two-fold: (1) it reduces the *area* of the loop, thus diminishing the amount of energy dissipated by hysteresis; and (2) it has the effect of tilting the loop towards the axis of magnetic induction. The abnormal hysteresis loop, to avoid too great complication, is omitted from Fig. 11; but in general shape it would not differ greatly from the dotted loop there shown, being merely somewhat smaller in area and tilted towards the vertical axis. The current rush in Fig. 12 is $\frac{1\cdot61}{0\cdot075} = 2\cdot14$, as against 2·45 in Fig. 10. Thus the effect of

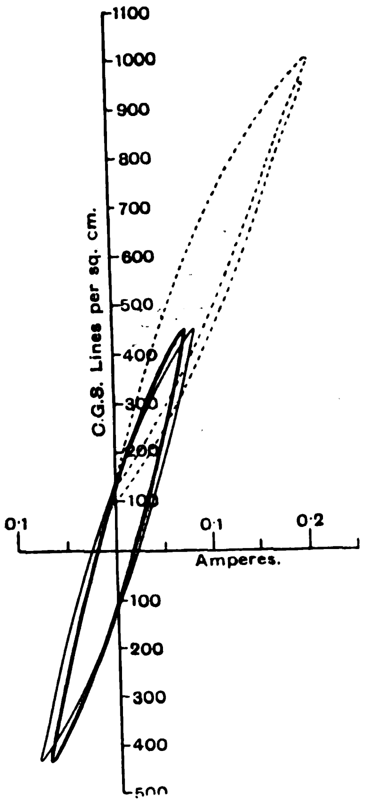

Fig. 11.

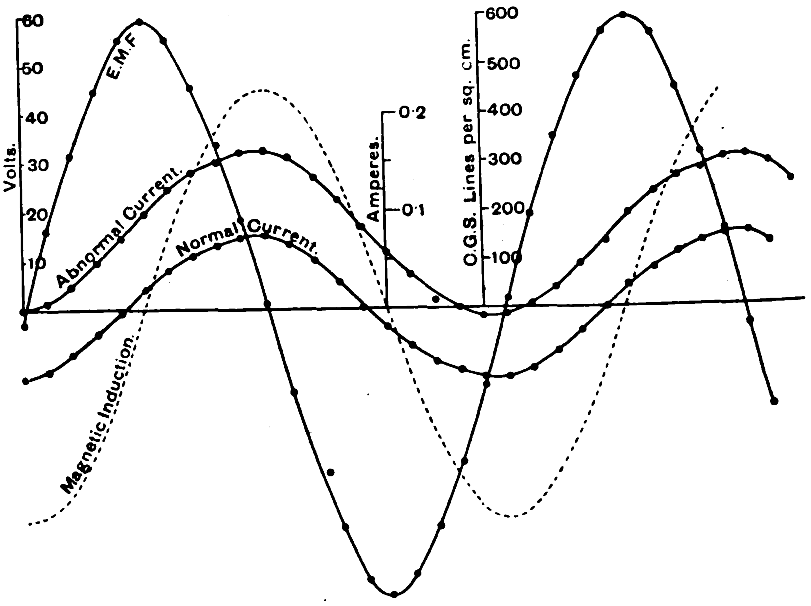

Fig. 12.

axis of magnetic induction a considerable distance above the starting point; in Fig. 11, on the other hand, the first descending branch practically passes through the starting point; (*b*) the second ascending branch of the abnormal loop in Fig. 7 crosses the first ascending branch; in Fig. 11 these two branches are almost parallel to one another, and the point of crossing is between the first ascending branch and the second descending branch; (*c*) the *shape* of the loops, both normal and abnormal, is widely different in the two cases.

The great reduction of the negative half-waves of current in Fig. 10 is very striking. During the first few waves, in fact, the current is all but unidirectional.

The greatest reduction of the maximum value of the abnormal current during the first half-wave which it was possible to obtain by varying the switching-off point amounted to 18 per cent., the extreme values being 0·2-08 and 0·17 amperes respectively.

The effect of altering the resistance of the circuit was also tried. The non-inductive resistance was reduced so as to make the total resistance equal to 2 02 ohms instead of 4·8. This was found to increase the maximum value of the abnormal current by about 3 per cent.

§ 20. It has already been mentioned that the readings for the curves of § 19 were taken after the transformer had been working at a much higher magnetic induction. The next experiment consisted in completely demagnetising the iron by the method of successive reversals, and repeating the read-removing every trace of initial magnetisation is to reduce the currents, normal and abnormal, the amount of energy dissipated by hysteresis, and the "current-rush."

(*To be continued.*)

ELLIPTICALLY POLARISED ELECTRIC RADIATION.

BY DR. OLIVER LODGE.

Since the delivery of my lecture to the Royal Institution, on June 1st, Herr Zehnder has published* a mode of getting elliptically and circularly polarised electric radiation. He takes a couple of plane-polarising grids, such as are depicted in Fig. 21, *The Electrician*, June 22nd, page 205, and places them parallel to each other at a little distance apart with their wires crossed.

If the two grids are close together they will act like wire-gauze, reflecting any kind of polarised radiation equally; but if the warp and woof are an eighth-wave length apart, and the plane of the incident radiation is at 45° to the wires, the reflected radiation will be circularly polarised. A change in the circumstances will, of course, make it elliptical. Such a pair of grids acts, in fact, like a Babinet's compensator.

THE INFLUENCE OF CIRCULATION ON EVAPORATIVE EFFICIENCY OF WATER-TUBE BOILERS.*

BY JOHN I. THORNYCROFT, F.R.S., VICE-PRESIDENT.

To obtain the highest evaporative duty from a given tube service, it is necessary that the contents of the tube should consist of, as far as possible, water only ; and to attain this result the steam must have the freest possible egress from the tubes, and must also be carried from them by an energetic circulation of water in a constant direction. To some of the leading features which affect these conditions I would now call your attention.

Considering the boilers shown in Figs. 1 and 2, if the pressure in the lower vessel—that is, at the bottom ends of the generating tubes—is that due to the full depth of water in the boiler, in

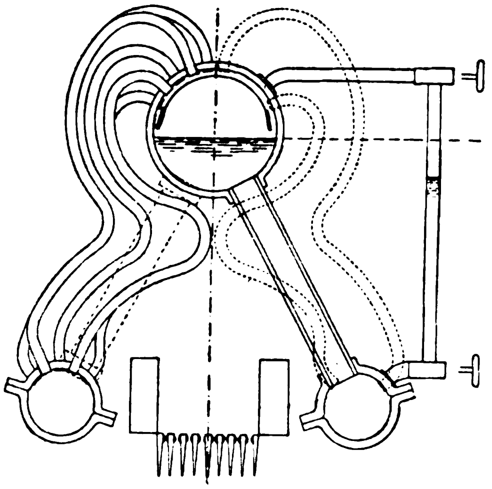

Fig. 1.

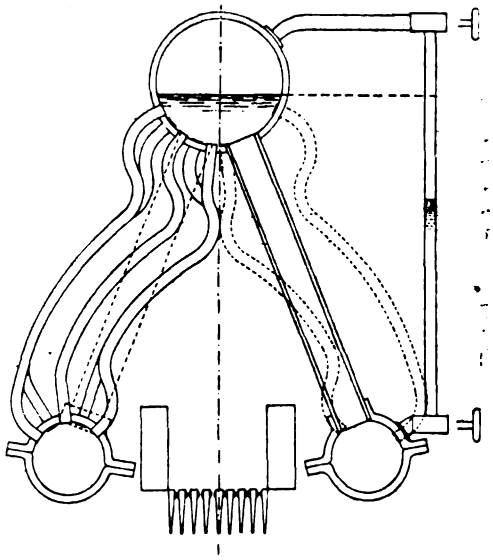

Fig. 2.

addition to the steam pressure, then any reduction of density in the generating tubes will all be available for causing circulation ; and thus any reduction in pressure in the lower vessel, below that due to the head of water in the boiler, is a direct loss to the energy of circulation, so that variations of this pressure are of great importance. These variations can be conveniently measured by a pressure column formed of a long gauge glass connecting the steam space of the upper vessel with the lower vessel. The difference of the water-level in this glass from the water-level in the upper vessel is a direct measure of any reduction of pressure in the lower vessel.

(3) Generating tubes delivering below water (without any special downtake tubes).

The curves given in Diagram 3 show graphically the results of these experiments ; the falls of pressure in the lower vessels are plotted as ordinates, and the rates of working as abscissæ. It will be seen that the rate of working has been taken up very high, probably more than double ordinary working, the object in doing this being to ascertain up to what rate each arrangement can be worked with safety. In the first series of curves the results recorded are obtained from the boiler (Fig. 1) with the generating tubes delivering above water. It will be seen from the curve that, as the rate of working is increased, the pressure column falls slightly, and at an evaporation of 20lb. of water per square foot of heating surface stands at 85 per cent. of the maximum ; and by halving the working pressure the results are not sensibly changed.

The next series of curves is taken from the boiler (Fig. 2) which has the same heating surface, &c., as Fig. 1, but the top ends of the tubes deliver below water. It will be seen that the curves fall much more rapidly than the first series, and that by halving the working pressure the pressure is distinctly reduced in the lower vessel.

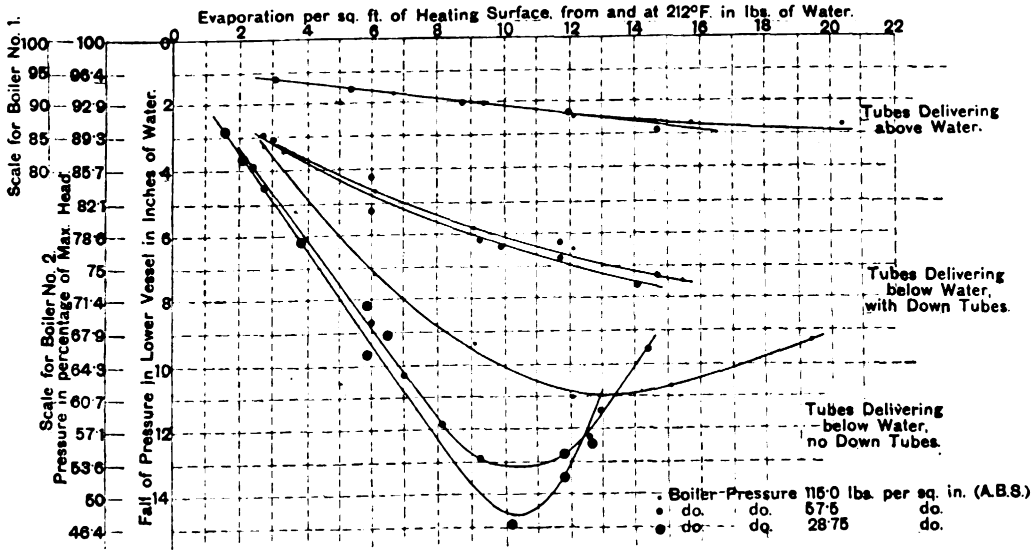

Fig. 3.

I have made experiments, taking observations from such pressure columns fitted to the boilers shown in Figs. 1 and 2, when they were working under different conditions. The rate of evaporation and steam pressure being varied for the several arrangements of boiler, which were :—

(1) Generating tubes delivering above water.
(2) Generating tubes delivering below water.

* Read at the Thirty-sixth Session (Summer Meeting) of the Institution of Naval Architects, 1894.

The third series was obtained from the boiler (Fig. 2) by plugging up the down-tubes, so that some of the generating tubes had to act as down tubes for the supply of the others ; the feed-water all being delivered into the upper vessel. In this case the character of the curves changes from the first two series very much. A diminution in pressure of working causes the pressure column to fall very much ; in the case of the pressure being only 28·75lb. per square inch absolute, it fell to about 46 per cent. of the maximum. The most important point, however, apart from this low pressure,

Digitized by Google

but a result of it, is that for any given pressure a critical rate of working is arrived at when the pressure column begins to rise again with increased rate of working, thus showing an increased pressure in the lower vessel, caused by the steam being unable to get out at the top ends of the tubes fast enough, and so comes out at the bottom ends as well.

It will be seen from the curves that the lower the pressure of working the sooner this critical point is arrived at, and I found that when the evaporation was pushed beyond this critical point the tubes were not safe from overheating; but, by taking the tubes intended for downtakes, and extending their upper ends above the water surface so that water could not go down, and the steam in the lower vessel could readily get away to the separator, it was possible to increase the rate of evaporation somewhat, inasmuch as the facility for the tubes getting rid of their steam was increased.

Contrasting the different conditions of working of the water-tubes in the three series of experiments I have described, and noting what slight differences these conditions may necessitate in the design of a boiler, the nearness to success which a boiler intended for hard forcing may be, and yet fail, is clearly shown.

In conclusion, I would submit that the absence of special down tubes limits to a great extent the amount to which a boiler can be safely forced, and shows that to obtain the highest rate of working with safety and efficiency these special down tubes must not be neglected; and, still further, the tubes should deliver above water, as then the circulation, as I have previously shown, is double that when the tubes deliver below water. So that this rapid circulation is a most important condition for hard working.

DISCUSSION.

The first speaker on this Paper was M. NORMAND. He said that it had been a matter of surprise to him how boilers of this type could have been worked without the down-comer tubes for circulation. The Belleville boiler, as first designed, had no return tubes, and the result was that sometimes the water got to the top, and the steam to the bottom of the boiler, which was by no means a desirable result.

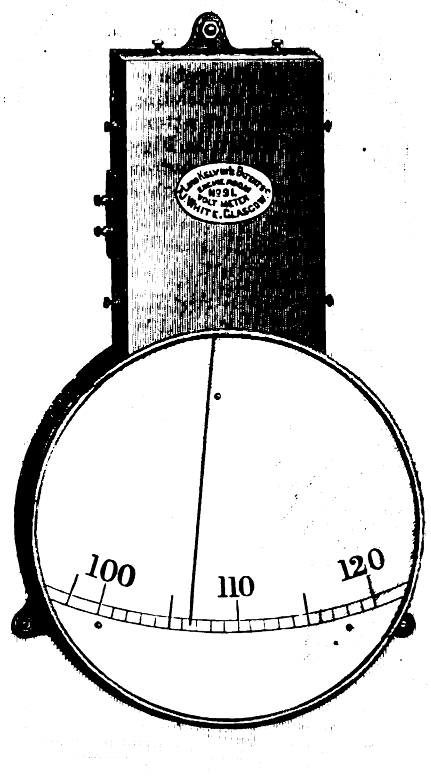
Mr. WATT said that, in the water tube boiler referred to by the author, the tubes were very small in diameter, and, therefore, they had to depend on rapid circulation. There might, however, be over-circulation in a boiler, and the consequent result would be over-heating of the tubes. In some of these boilers the tubes had been galvanised internally, and the zinc had decomposed the steam. He thought that the same action occurred in a lesser degree with iron or steel tubes, and so, unless means were taken for stopping the over-heating of the tubes, the life of the boiler would be very short.

Mr. PILCHER, referring to the question of circulation in water-tube boilers, described the means adopted by Mr. Maxim in the boiler of his flying machine. This boiler was of the Thornycroft type, the generating tubes being of excessively thin copper, and $\frac{3}{8}$in. in diameter. The maximum horse-power was 300 indicated, the pressure in the boiler being 300lb. to the square inch, and the weight of boiler 3lb per indicated horse-power. With the excessively high rate of evaporation and thin tubes, it was found impossible to produce sufficient circulation to keep the tubes from burning.

Mr. THORNYCROFT, in replying to the discussion, said he was afraid that he had not fully explained himself in the Paper, as he gathered some of the speakers had not quite grasped his meaning. Referring to the device described by Mr. Pilcher, he thought that for ordinary purposes it would not be advisable; and he was of opinion that if the generating tubes were not excessively long they could be worked at the small diameter Mr. Maxim had adopted. That is to say, at 300lb. pressure the tubes could be made to stand at $\frac{3}{8}$in. in diameter, though doubtless the fact remained they had broken down in the instance referred to. He himself had found that a $\frac{3}{8}$in. tube could not be burnt in a smith's fire, even working at atmospheric pressure. In steam-generating tubes of large diameter there would be no change in the water due to circulation, for the steam would find its way through the water when working slowly. Mr. Watt had said there might be over-circulation, but that the speaker looked on as impossible. In a water-tube boiler constructed on his principle by his firm the tubes had been worked five years, and at the end of that time they had been found still good. They were originally 15 B.W.G., and when taken out were 16 B.W.G., there being no evidence of local pitting. These were steel tubes.

LORD KELVIN'S LARGE DIAL VOLTMETER.

The large dial voltmeter is quite the same in its principle and action as the ampere gauge, but is fitted with an arrangement by means of which the instrument does not give indications through the part of the scale which is not required, and the part which is necessary is made very open. This is managed by means of a weight which is lifted by the soft iron plunger when it is a little above its zero position. This weight is made heavy enough to hold the plunger down until the voltage reaches the desired point, when the plunger lifts the weight off its support and begins to indicate. For example, an instrument which is intended to work at 100 volts would have its weight, and would not be able to lift it till the E.M.F. rose to 90 volts. The instrument would then indicate on a scale of very large divisions from 90 to 110 volts. The desired range of the instrument can be made to suit any circuit where a short open scale is required, such as from 90 to 110, 95 to 105, or from 100 to 120 volts. The main advan-



tages are that the instrument uses only a small current, though it has a quick action and is very free from friction. It gives a large open scale only at the part required, and has a clear zero indication. The space between divisions on a scale from 90 to 110 or 100 to 120 fully $\frac{1}{2}$in.

ON MAGNETISATION OF HOLLOW OR SOLID CYLINDRICAL CORES.*

BY H. DU BOIS.

The vexed question of hollow *v.* solid cores is once more discussed in this note. Von Feilitzsch's well-known result that the magnetic moment of short hollow cores is hardly inferior to that of solid ones (other circumstances equal, and saturation not being approached) has been elegantly explained by Prof. Silvanus Thompson in a general qualitative way by the simple remark that the external air resistance is approximately the same in both cases. There is no need whatever, therefore, for the assumption that the central fibres of cores are less easily "reached" by steady magnetisation than those near the skin; such a state of things would only be proved if the same result were obtained with hollow endless rings, which is improbable.

Von Feilitzsch's experiments having been lately repeated and extended by Prof. Grotrian (*Wied. Ann.*, 50, p. 705, 1893), the author seizes the occasion for attempting to go into the matter a little more fully. The particular case of a cylinder being one of those, in which the modern "magnetic circuit" notion does not lead up to quantitative results so well as the more orthodox theory of induction, the latter had to be applied, and immediately yielded the following general rule:—

If for cylindric or prismatic bodies of given length and any shape of section the "demagnetising factor" be proportional to the latter, and not too small, then the magnetic moment will be practically independent of the section for fields, which are not so strong as to produce an approach towards saturation.

It is further shown that both *præmissæ* of this rule apply to thin hollow cores, for which it is thereby easy to draw the curves of magnetic moment and impressed field up to thorough saturation for any given dimensions. An illustrative diagram of such curves is given, which presents exactly the same aspect as the experimental diagram of Prof. Grotrian's Paper. Finally, the question of hollow cores for dynamos is touched upon. Signor Ascoli has since independently criticised Prof. Grotrian's results much on the same lines.

RING-ELECTROMAGNET FOR PRODUCING STRONG FIELDS.*

BY H. DU BOIS.

The large ring employed, made of the best Swedish iron (50cm. mean diameter, 10cm. thickness) is slit radially in one place, tangentially in another, so that the width of the former air-gap may be conveniently varied. It bears 12 coils, each having a resistance of 0·2 ohm, and covering 90deg. (1/18) of the circumference; by means of these a maximum magnetomotive force of 108,000 ampere turns may be applied, requiring about 6·5 H.P. The highest value of the inductance is about 180 henries, corresponding to a "time ratio" of 180/2·4=75 seconds; the mean values are, of course, less. Ballistic measurements are, therefore, out of question.

When provided with flat pole-pieces the apparatus represents the simplest possible type of magnetic circuit, and is, therefore, well suited for an experimental verification of its laws. By a special method, which is described *in extenso*, the author was able to verify his form of the theory of magnetic circuits (*Phil. Mag.*, Nov., 1890, *Wied. Ann.*, Vol. LXVI., p. 491, 1892) with sufficient approximation. The leakage was roughly determined by a compass; its absolute amount was found to reach a maximum for a comparatively low magnetising current, and to *diminish* considerably as the current was increased. This final decrease of leakage, which, of course, is more marked still when referred to unit flux of induction through the circuit was previously found with a smaller ring by H. Lehmann (*Phil. Mag.*, April, 1893) and discussed by the author (*The Electrician*, Vol. XXIX., p. 450, 1892). It was explained how this simple fact constitutes an *experimentum crucis* against the fallacy of assuming—arguing from analogy with a voltaic battery immersed in an electrolyte—that leakage must always increase when saturation is being approached. It was also found that leakage is considerably diminished by the ampere turns near upon the air-gap; these "pole coils," as it were, fulfil the useful function of keeping the flux of induction together, preventing the lines from spreading.

The principal object of the apparatus is the production of strong fields by concentrating this flux through properly-shaped pole-pieces. A theory of the latter was developed almost simultaneously (1888) by Stefan and Ewing and Law, in which the assumption of absolute saturation is made. As this condition can never be fulfilled in practice, the author redetermined the best shape for the poles in an empirical way; it was found—in good accordance with Prof. Ewing's prediction—that it is best to take a straight truncated cone of semi-vertical angle 60° (instead of the theoretical 54° 44′).

The field obtainable in air with such pole-pieces falls short of the theoretical value by several thousand units; however, it beats the previous record † (about 30,000 C.G.S.) by a considerable amount. It was found

for a=5mm. H=36,800 C.G.S.
for a=3mm. H=38,000 C.G.S.

where a denotes the diameter of the small truncated faces.

To give an idea of this field the author points out that a bit of good thin iron wire would easily get saturated up to I=1750, corresponding to an induction

$$B=38{,}000+(4\pi\times1{,}750)=60{,}000 \text{ C.G.S.}$$

This corresponds to a tension of $B^2/8\pi$ dynes per cm.^{2} or 144 kilog.-weight per cm.^{2} A concentrated aqueous solution of ferric chloride in a U-tube (Quincke) would be lifted about half a metre; finally the resistance of a bismuth spiral would be nearly trebled in this field.

The author concludes that it is possible to obtain fields of, say, 40,000 C.G.S. with ring electro-magnets of reasonable size; but that stronger fields can probably only be reached by means out of all proportion with the purpose in view.

* *Wied. Ann.*, Vol. LI., p. 537.

[† We alluded to this fact on p. 541, Vol. XXXII.—Ed. *E.*]

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July* 23, 1894.

Underwriters' Rules.—About two years ago, at the initiative of Mr. C. M. Goddard, of the New England Insurance Exchange, a meeting of electrical insurance inspectors was held, where the subject of a national set of insurance rules was taken up, and the Underwriters' International Electric Association organised to furtheir their adoption. Taking a set of excellent rules for safe wiring prepared by the National Electric Light Association as a basis, a tentative code of insurance rules was drawn up and submitted to the various underwriters' associations for criticism. At subsequent meetings proposed changes were discussed, and, finally, a definite set of rules adopted and offered to the various underwriters' associations throughout the United States for adoption. With scarcely an exception the rules have been welcomed by insurance companies and associations, and their adoption by the Southern Tariff Association a few weeks ago brings almost the last of the general underwriters' organisations within the fold.

Railway Networks.—Rumours are again current in the daily Press in regard to a great electric railway "network" between Camden, opposite Philadelphia, and Jersey City, opposite New York. According to the printed accounts, a main electric line will be built, and all of the towns in the State of New Jersey between the places named, which are about 90 miles apart, are to be inter-connected, and all act as feeders to the trunk line. It seems probable, however, that the real object of such projects is to secure more favourable terms from town governing bodies for local franchises. The term "electric railway network" seems to have a charm for the public, only approached by "long distance electric traction," which also, it is to be feared, is made to serve ulterior ends.

CORRESPONDENCE.

VACUUM TUBE EXPERIMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Sir David Salomons' letter of the 19th inst. suggests the thought that, perhaps, he did not trace out his connections for continuity before assuming that no light was produced by the passage of a current through a vacuum. Was there any indication of heat? What proof of an actual current flowing was there?—Yours, &c. L. PYKE.

34, New Tothill-street, Westminster, S.W., July 28, 1894.

THE SHARP FLY-WHEEL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to your article on "Central Station Practice" in your last issue, I think you have failed to realise that the conditions to which the rim of a fly-wheel such as I propose would be subjected are entirely different to those to which the rim of a cast iron wheel, with a small number of arms, is subjected.

The rim of a fly-wheel is simply a metal ring rotating rapidly about its geometrical axis, and the stresses to which it is subjected are principally due to centrifugal force. If the rim of the fly-wheel be subjected to no constraint by the arms, and its speed be 100ft. per second the circumferential tension will be less than half a ton per square inch. Now, it is well known that 100ft. per second is a dangerous speed for cast-iron fly-wheels of the usual type with a small number of arms. The difference between this low stress and the breaking stress of the material is supplied by the bending stresses on the rim due to the constraint of the arms. Now, in my fly-wheel "the rim being supported at small intervals by the numerous spokes is nowhere subjected to large bending stresses due to centrifugal force, as in the case of large wheels with a small number of arms; it may, therefore, be run at a much higher velocity with safety." In fact, the bending stresses vary directly as the square of the distance between the ends of the arms or spokes, and, therefore, inversely as the number of spokes. Thus, in a wheel of a given diameter, if in my design the spokes are four times as numerous as the arms in the usual design, the bending stresses due to centrifugal force will be only $\frac{1}{16}$th of those in the usual design. At a speed of 300ft. per second the centrifugal stresses in the rim, considered unconstrained by the spokes or arms, will be 4·2 tons per square inch, which seems a low enough stress for mild steel. But the actual stresses in the rim while the wheel is rotating can be reduced by simply putting an initial compression on the rim by tightening up the spokes; in fact, by using a sufficient number of

Digitized by Google

spokes the stress in the rim may be reduced to zero, the centrifugal force being taken up directly by the spokes.

I think if my flywheel design be carefully considered it will be seen that a speed of 300ft. per second will be safer than a speed of 100ft. per second with the usual type of flywheel. I beg to enclose a pamphlet in which I give a short analysis of the stresses in my flywheel, a copy of which I shall be glad to send to any engineer interested in the question.

As a matter of fact, the above speed has been exceeded in "Parson's Steam Turbine," where the material is necessarily less advantageously disposed to resist the centrifugal stresses.

Yours, &c., ARCHIBALD SHARP.

London, S.W., July 30, 1894.

LEGAL INTELLIGENCE.

Woodhouse and Rawson United (Limited).

FRIDAY, JULY 27TH.

The REGISTRAR having asked Mr. F. L. Rawson (who was again sworn) as to the reasons of his leaving out from the circular announcing the retirement of three of the first Directors the statement which they wished to have inserted that any applicant might withdraw his application,

WITNESS said it certainly was not an accident that it was left out, as the point was most carefully considered. He certainly told Mr. Johnson of the minute, and was much annoyed when he first heard it said that he ought to have seen Mr. Budd, and not Mr. Johnson, because he felt that he had done all that he ought to do in the matter.

A SOLICITOR said he had asked Mr. Johnson about this point, and he said he could not recall the circumstances after this lapse of time, but he certainly would not have passed a circular of that kind had he known of the special nature of the Board minute.

The OFFICIAL RECEIVER said in the balance-sheet of 1891 there was included an item of £2,640. 11s. 3d., being, according to the description in the journal, surplus assets of the Kidsgrove purchase. There were £1,000 in 1890, and £2,640 in 1891, under this heading. Mr. Pilling, who was the auditor of that branch of the business, had reported that the surplus shown was "a fictitious surplus."

WITNESS said that was certainly not the case. It was the result of a re-valuation after the purchase, when it was found that the plant and stock came out at £3,640 more than was paid for it. In 1890 the Directors felt uncertain as to this matter, and determined only to include £1,000 on account of this surplus; but the next year it was found that the revaluation was undoubtedly correct, and the remaining £2,640 was then included in the accounts.

The OFFICIAL RECEIVER: Was the report of the auditor read to the Board?—I do not think so. It was a surprise to me to learn that there ever was a report at all. I found that Mr. North purposely kept back this report from me. Mr. North opened the letters at the offices.

Mr. STUTCHBURY was recalled, and asked by the Official Receiver if he had ever seen the report in question. He said he remembered seeing it. It came at the same time as the audited balance-sheet was received. He did not think there was any concealment of the report, and he was under the impression that it was brought either before the Board or the Finance Committee. Mr. North showed it to him. He would not like to say that Mr. Rawson ever saw the report, but he had the opportunity of seeing it. He could not see that Mr. North had any reason for concealing the report.

By Mr. Jenkins: He was at most of the meetings of the Board and of the Finance Committee, and usually drew up the minutes, although they were subjected to revision and alteration by the Managing Director and Chairman. He could find no reference to the report in the minutes of either the Board meetings or those of the Finance Committee.

By the Registrar: The minutes may sometimes have been curtailed; he would not go so far as to say that anything was ever struck out.

By Mr. H. G. Rawson: If his draft of the minutes had stated that this report was read, and the minutes as ultimately entered omitted such reference, he would undoubtedly have called the Board's attention to the fact.

By the Registrar: He could suggest no reason, if the report were laid before the Board, why there was no record of the fact in the minutes.

By Mr. F. L. Rawson: The Board were extremely surprised to learn that advances had been made to Messrs. King, Masterman and Terry, the vendors at Kidsgrove Works, to which there was reference in Mr. Pilling's report. It might have been the case that if they had known of these advances, which were known to Mr. North, it would have led to Mr. North's affairs being closely looked into; but he believed Mr. North himself informed the Board of the matter towards the end of his time.

Mr. F. L. RAWSON'S examination was then resumed. He still adhered to his statement that he had not seen the report until the commencement of the winding-up proceedings. He thought Mr. Stutchbury had made a mistake in regard to the date at which he saw the report; witness had heard something of the report having been discovered amongst North's papers. Replying to further questions regarding the Kidsgrove accounts, witness said the amounts written off on account of losses at the works had no connection whatever with the surplus of £3,640. There was no doubt at all but that Messrs. King, Masterman and Terry had made a mistake in their valuation of plant and stock; they had gone on purchasing new plant and stock, regarding which there was no entry in their books, and when they estimated the book values of plant and stock they overlooked this new plant and stock. He saw no reason whatever why they should not take credit in the accounts for the mistake of the vendors. One item referred to a sum which was paid into King, Masterman and Terry's account by a firm who had formerly had business with them instead of being paid into the United's account. King, Masterman and Terry admitted the facts, and said they were very sorry, but that it was done with Mr. North's knowledge. So careful was he with regard to the purchase of Kidsgrove that he went fully into the financial position of Messrs. King, Masterman and Terry, and he found that by the statement made out their assets amounted to £75,000, and their liabilities to about £35,000 or £40,000. A certain part of their assets, however, consisted of Barbadoes debentures, which were taken at par, and those debentures turned out practically unsaleable. Had he seen Mr. Pilling's report he certainly would still have allowed the item £2,640 to appear in the accounts in the way it did, as it was a question of plant and stock. The Directors were aware that there was a loss on the Kidsgrove works, but may not have known the exact amount. With regard to the Phœnix Trust Company, the Founders' shares held by the United Company were acquired for £25, and were valued in the balance-sheet of 1891 at £15,000. The Phœnix Trust paid a dividend of £1,465 in cash in January, 1891, and in May of that year a dividend of £5,160 in shares in the Austrian and French Elmore Companies. Those were the only dividends paid by the Phœnix Trust Company. Witness did not know whether those shares had only realised, up to the present time, £3,295. Woodhouse and Rawson United really had nothing to do with the promotion of the companies named. On the whole of the transactions with the Phœnix Trust they had taken in the accounts a profit of £36,658, but had only realised up to the present about £9,000. Witness had himself been offered £10,000 for the United Company's holding of 25 founders' shares, and he conveyed that offer, which was made by Baron Grant, to the Board, who, however, considered that if the shares were worth £10,000 to Baron Grant they were probably worth much more to them and declined to part with them. They arrived at the valuation of these shares at what they were taken in the balance-sheet by an investigation as to what would be the amount of their share of the assets of the Phœnix Trust Company if that company were wound up at that date, taking everything at the current market price, there being a quotation of nearly all the shares concerned. This investigation showed that their share would be £20,000, but the Directors decided to put it in at £17,500. Subsequently, at their request, witness again went into the affairs of the Phœnix Company, and found that he had at first omitted a liability of £2,000, of which he had not known. To guard against over-valuation, and the possibility of other mistakes having been made, the Directors then decided to put the value of the shares in at £15,000. It might be taken that the whole of this £15,000 represented entirely holdings in the Elmore Companies. There was once a mistake in regard to the meeting of a bill by the Phœnix Trust Company, the money having been paid in to the wrong bank, or something of that kind; otherwise they always met their bills when due, unless they were renewed. The Phœnix Company complained that the reason why the Elmore Company did not pay a dividend was that it was mismanaged by the Directors, for which they blamed the United Company. The rebate of £12,000 on the guarantee fund was also taken in as a profit. This represented the return to the Limited Company of £63,000 in lieu of £75,000, the full amount of the guarantee, in consideration of its being paid 18 months in advance. The result of that was that they had to borrow from their bank to the extent of £13,000 at an average rate of interest of 7 per cent., and this interest, together with the payments on the £50,000 worth of Five and a-Half per Cent. Debentures, amounted to £3,660 for one year, and in the accounts for 1891 they omitted any consideration of the fact that they would have to pay that sum in the next year; this was a very involved point, and he could not say that he really understood why that was not charged.

The OFFICIAL RECEIVER: You were taking credit for your financial profits for 13 months, and you were only debiting yourself with your losses on the industrial business for 11 months, so it is a fair criticism, is it not? to say that had you made your year for the industrial business end at the same time as that of the financial business, there would have been an additional loss to put in of another £4,000?—No, because we gave the whole of the charges for the 13 months. There might have been a small loss, but not so much as that.

Examination continued: His communications with Baron Grant, of the National Financial Corporation, practically ceased before the date of the passing of the resolution by the Board calling upon him to discontinue those relations. The Merxem Company, with which he afterwards had dealings, had nothing to do with the National Financial Corporation. The reason why the bringing out of the Epstein Company was deferred till the last day of the year was that he was in constant negotiation with regard to the matter, and getting better terms the longer the matter was deferred. The business might have been closed at the end of May or the end of June as easily as at the end of July; but then the United Company would have had far less beneficial terms. There were two independent Directors on the Board of the Epstein Company, and it was with them that terms were arranged. To the best of his knowledge and belief the Epstein Company was capitalised at a lower figure than any other accumulator company. They paid only £70,000 for the whole of their patents, whereas their chief rival paid something like £300,000 or £400,000, and the patent for England alone stood in their books for something like £70,000. Mr. Epstein went to America with a power of attorney to sell the patents for that country for £20,000, and the Thomson-Houston Company sent over an expert, who made a long report; he was absolutely satisfied on every point with the exception of two, which were the applicability of the accumulator to the purposes of

Digitized by Google

traction, and the cost. They claimed then that the cost did not exceed 1d. per car mile, 2d. per car mile being the accepted figure, which rendered traction commercially possible by means of accumulators; subsequently they found the cost with the Epstein accumulator was as low as ½d. per car mile. The original cells used at Birmingham were still running, and were thoroughly satisfactory after 21 months use. His recollection was that Mr. Epstein told the Board that £50,000 had been spent in bringing the invention to its present state, but Mr. Epstein now said he did not mention quite so large a figure as that; he said £30,000 had been spent apart altogether from what they (Woodhouse and Rawson) had spent on it. Then Mr. Stepney Rawson, as well as witness himself, had spent an immense amount of time for over a year, and this would bring up the value of the patents a good deal. They had a report from the late Mr. Reckenzaun, perhaps the leading expert upon accumulators, and himself an inventor of one, who said that the Epstein was as good as his own on all points, and better in many. If the capital had been paid into the bank so that the Epstein Company could have used it as they wanted it, the position of the Company would have been very different from what it was now, but Woodhouse and Rawson United could only deal out the money in driblets. There was a fire at the Epstein works, which threw them back 18 months.

After the luncheon interval,

Mr. PHILIP RAWSON was re-called, and said the date given at his previous examination as that at which he first learnt of the connection of the Managing Director with the Phœnix Trust was incorrect, and he should have said 1891 instead of 1892. He did not think he knew in September, 1890.

Sir JOHN STOKES was also re-called, and said he was not present at the meeting of the Board in September at which Mr. Rawson gave the explanation referred to on the minutes concerning the Phœnix Trust Company. He certainly had knowledge of the interest of the Managing Director in the Phœnix Company; but when that knowledge was first gained he could not quite say. He was not aware, until he heard it in court, that practically the whole of the Phœnix Company's shares were held by Mr. and Mrs. F. L. Rawson, Baron Grant and the National Financial Corporation.

Mr. F. L. RAWSON, in further explanation of Epstein matters, said it had been inferred that the profit made by the inclusion of the Epstein shares would not have come in in the 1891 balance-sheet had they not taken the financial business up to the end of July. The reason for the closing the year's accounts on one side of the business at one time, and the other at another date was that Mr. Pixley suggested that, in order to get over the difficulty of the long time it took to get the accounts from the outstanding branches, they should take those branches in the following year up to the end of May, and it was settled to do so; then it was considered by the Board best to take the whole of the industrial branches up to the end of May, instead of part to May and part to June or July.

By the OFFICIAL RECEIVER: If it had not been for the stingy way in which the United Company dribbled out the money to the Epstein Company all might have been well with that Company. As it was £13,280 was "dribbled out," but £4,000 of that was paid before the Epstein Company was formed, and the last payment was a long time afterwards. At a meeting of shareholders he was asked about cheques and cash in hand, amounting to £31,000, and he replied that that was in consequence of one cheque for £30,000 which was not paid into the bank on the actual night of the closing of the balance-sheet. His impression was that that cheque was paid in two or three days afterwards.

The OFFICIAL RECEIVER: Were you aware that the reason was that there was no balance to meet it?—No, that was not the case. There was plenty of money to meet it without the application money of Woodhouse and Rawson.

If I show you the banking account of the Okonite Company, showing that they had not the funds, would that affect your answer?—Not at all.

Do you suggest that the cheque would have been honoured if presented on the day after?—I do not suggest it.

Were you aware that it would not?—I do not know. I think probably it would have been.

Why did you hold it over?—Because it was agreed with the Okonite Company. They had to pay us by a certain date, but asked me not to present the cheque just at once. It is true that about £6,000 was paid in by Woodhouse and Rawson subsequently.

By Mr. Squire (a shareholder): The profit on the Okonite promotion was entered in the balance-sheet for 1890, although it was not actually received until two months later. The profit was properly made in the year ending June, 1890, and they were advised by counsel that it was quite proper that it should be entered in the books as belonging to that year. Had it not been entered that year the profits of course would have been less, but not to the extent of £37,240, as Mr. Squire suggested. He offered, as that profit was partly made in shares and debentures, not to take his percentage at all that year, but to wait until those shares and debentures were realised, or he was willing to take his commission in shares and debentures at the price at which they stood in the balance-sheet, and it was decided that that should be done. He also stated that if they thought his contract an unfair one he would cancel it altogether, and make any other contract they might wish. In the second year the value of their holding in the Phœnix Trust was estimated upon the same principle as in the first; they estimated they would receive £9,000, but as a matter of fact they received £12,000. Asked why the Phœnix Trust was formed, witness said the Directors of the United asked him to endeavour to sell the Elmore shares that they held, and he approached various Trust Companies, but was unable to get the price they wanted. At almost the same date an offer was made by some people in the City to bring out the French Elmore Company. He had been asked to see if the Directors of the United would bring out that Company and underwrite it, but he said they certainly would not. He asked them, however, but they refused. He thought he might be able to get a profit for the United if they would allow their name to be used on the prospectus as having looked into the proposed company and satisfied themselves on the technical points. He went to one or two Trust Companies, who made offers which were refused, and he then got up a syndicate consisting of about 30 City people to find the necessary money to purchase the Elmore shares from the United and underwrite the French Company, and all those people took shares. Those people not only insisted that he (Witness) should become a Director, but also that he should give them assistance and advice, and offered him a large number of Founders' shares if he would oblige them. He reported all the facts to the Board. When Mr. Phillips, Chairman of the Syndicate, saw Witness's father, he mentioned Baron Grant's name, and Sir Rawson asked what his connection with the Trust was, Mr. Phillips replying that he wanted to become a shareholder. When the others went out of the Phœnix Company he got Mrs. Rawson to take a thousand shares, took a thousand himself, and Baron Grant also took a thousand. Woodhouse and Rawson United required a deposit at the time the contract of purchase was made, and that deposit was made. Witness lent the Phœnix Company £5,000, and took payment in paper. He got a trifle more than the United did when the Phœnix Company was wound up in consequence of his holding Ordinary shares.

By Mr. Pilling: Woodhouse and Rawson United made no advances to the Phœnix Company. They paid the expenses of the promotion: but that was after the Company was a successful one, and there was no risk whatever. The United never ran any risk in any promotion, either directly or indirectly.

The further examination was adjourned till Monday next, August 6th.

Cassel Gold Extracting Company v. The Cyanide Gold Recovery Syndicate, and Others.

In the trial of this action, which was continued before Mr. Justice Romer, evidence for the defence was taken.

Mr. CLAUDE VAUTIN said that he had been an analytical chemist for over twenty years, and had applied himself to the study of gold. Sixteen years ago he knew of the solution of gold by cyanide of potassium. It should have been known to persons engaged in metallurgical chemistry in 1887 that cyanide of potassium dissolved gold in a state of fine division. In 1855 he was in Melbourne, and was then acquainted with Sanders's patent. He carried out experiments on the lines of the patent. A number of patents was tested, and Sanders's was thought to be an extraordinary one—the extraordinary thing was that Sanders should use an acid which would dissolve gold. Witness gave the results of some experiments with cyanide of ammonium and cyanide of potassium, and said he found that that mixture acted on natural gold quicker than the plaintiffs'. He had dealt with, or seen dealt with, thousands of tons of ore. Witness described experiments he had made with two beakers, into each of which a solution of 7 per cent. of cyanide of potassium and some water were put. In one beaker a piece of gold leaf was suspended between two pieces of muslin, the same as in the other. In one beaker he introduced an electric current, and passed it from the anode to the cathode. The time was taken, and the gold leaf with the current broke up and became disintegrated five times quicker than in the other. Faraday's method was followed, and there was no possibility of connection between the anode and the gold leaf. He found that Faraday's principle was perfectly correct. The gold leaf submitted to the electric current was broken up, and it rapidly dissolved in the muslin bag. In another experiment the result was that the gold was not found on the cathode. He believed that if Rae's directions were carried out they would dissolve suitable ores. He had no hesitation in saying that gold would go into solution by that process. That would take place if the electric part were operative or not.

It was his opinion that electricity helped the process of solution.

The best paper on the solution of gold by cyanide of potassium was Dixon's; but Rae and Simpson knew the process also. Simpson had no gold anode; Rae proposed physical contact, and the solution of the gold in the same way as the electro-plating process. Witness had not put forward Sanders's process as disclosing new knowledge. With respect to his experiments with the two beakers, it was very difficult to get two leaves of gold of exactly the same weight, because the gold was so very thin. He used four cells and 7 volts electricity. The gold disappeared to a great extent. It was not, he thought, a fact that the mere passage of the current would break down the gold leaf with that pressure.

Mr. R. H. HARLAND, F.C.S., said he had conducted experiments in respect to the process of the defendants. The object of these was to ascertain the difference in the gold dissolved in ore when electricity was used in tank "A" and when it was not. He began experimenting with 2lb. of ore, and increased it to 4lb., and then to 25lb. He assayed the ore he used before it had been through the process and afterwards. Where the electrical current was present the amount of gold extracted was 83·4 per cent., and in the case without the current 73·6 per cent.—a difference, roughly, of 10 per cent. in favour of the employment of the current. His last experiments gave better results than the former. In the course of his experiments he used the defendants' apparatus. The electrodes were of the full size. Witness challenged the results of Mr. Tatlock's experiments on the ground that it was unsatisfactory to assay the tailings. The error was so great as to nullify the results. A large quantity of ore gave more reliable results than the small one which Mr. Tatlock took. With regard to the selective operation of cyanide of potassium, witness said that the operation began on the baser metals at the same time as on the gold. With regard to his experiments with defendants' apparatus, the apparatus was about the same size as the model in Court. What he operated upon was ore, not tailings. The object of the experiment was to see whether

Digitized by Google

electricity had any effect. The experiments with electricity were made with the Pielsticker process, and the experiments without electricity were made in a separate vessel. In the former experiments he had circulation, and in the other he had no circulation, but stirred up the ore.

Mr. Justice ROMER asked why the witnesses did not take the test in the ordinary way; that was to say, take Pielsticker's machine, work it for 24 hours with a current of electricity, and then 24 hours without the current, and then see how much more gold was deposited in the one case than in the other. He did not see why the experiment should not be tried if both parties were agreed that it was important. He did not say that it was essential to decide this case; but, still, it might be. It would, however, be an absolutely certain test to find whether electricity did produce more gold or not.

Mr. RILEY, F.C.S., F.I.C., said that it had been known for many years that cyanide of potassium would dissolve gold. It required no inventive faculty to know that cyanide of potassium was a solvent which would operate upon gold ore; it was simply the application of a well-known chemical solvent under special conditions. Rae's process would be operative for the purpose of dissolving the gold if the gold were in a fine state of division. Simpson's also would be efficient. Prior to the plaintiffs' patent the knowledge that cyanide of potassium could be practically used to extract gold from ore was scattered through all the chemical books. Perhaps the electricity in Rae's process would not have much effect. He preferred to leave the electrical part to the electricians.

Mr. Justice ROMER: Would any chemist in the beginning of 1887 have felt any doubt that a solution of cyanide of potassium would have dissolved that gold and silver?—I should have had no doubt myself.

Mr. JAMES MACTEAR, F.I.C., said that in 1887 the fact that cyanide of potassium would dissolve gold and silver was well known. There was no invention in the application of that knowledge to gold ore. Witness was present at the experiments of the defendants, the result of which, he said, was that the gold was dissolved more rapidly when electricity was used. Rae's process would be effective for getting gold into solution, but it was impossible that it could be a financial success because of the difficulty of getting the gold out of solution. Cyanide of potassium had been reduced in price from 17s. per lb. to 1s. per lb. Faraday disclosed as much as any of the extracts relied upon in the particulars of objection, but in chemical literature there were more specific references to the solubility of gold in cyanide of potassium than those which the defendants relied upon. In 1885 the price of the cyanide of potassium he would use for this process would have been 2s. 6d. per lb. He considered that the electrical pressure and current with which Lord Kelvin worked was too small to produce any electrical result. In 1887 the process of getting the gold out of cyanide by zinc was not practicable—that was to say, only some of it could be got out.

Prof. ATTFIELD, F.R.S., said that he had read a Paper on the solution of gold by cyanide of potassium before the Chemical Society thirty years ago. Rae's process would dissolve gold. He thought that in that process the cyanide of potassium was the main agent, and he inferred from the language used that the electric current was only to materially facilitate the action. He did not find any indication in Rae that a person was to abandon his electricity and get his gold by means of a solution of cyanide of potassium only.

This was the case for the defendants, and Mr. NEVILLE on their behalf said they were sufficiently satisfied with their lines, and did not desire to have any further experiments on the question of electricity.

Mr. Justice ROMER: You will try the case on the same footing as if you had not used electricity?—Yes.

Mr. NEVILLE then summed up the case for the defendants. They might, he said, have gone on almost until Doomsday about electricity, but there was one broad point. The plaintiffs claimed the use of any solution which contained cyanogen or cyanide, or any cyanogen-yielding substance. If that were so, that obviously applied to Simpson and to Rae, who both used a cyanogen-containing solution for the purpose of extracting gold from ore. There was an end of the case. He proceeded to attempt to dispose of the argument that the plaintiffs' was such a meritorious invention that it ought to be favourably viewed by the Court. Not one ton of gold ore was treated until the plaintiffs had arrived at a suitable method of getting the gold out of solution. If the plaintiffs' patent was not for the use of cyanide of potassium alone, then Simpson's patent was fatal to it, because there there was only a slight admixture of another chemical. All the evidence went to show that Simpson's patent would do the work of the plaintiffs' patent, and it was an absolute absurdity to say that all the world might use cyanide of potassium if they put in half an ounce of carbonate of ammonium, but that the plaintiffs alone had the use of cyanide of potassium. Having dealt with the sort of publication necessary to anticipate the patent, he now proposed to examine the existing state of knowledge from the points of view of what the general knowledge showed and what specific exposition showed. It was common ground that there was no prior user in this case.

Mr. Justice ROMER: In England.

Sir R. WEBSTER said he should show that there was evidence of no user of Simpson or Rae anywhere in a sense that would invalidate the patent. The two most important points in this action were the alleged anticipations of Rae and Simpson. The defendants, he said, came into Court to win this case upon Rae's specification; they came to prove that they were electrically depositing the gold out of the ordinary solution, and not using the chemical action. He did not hesitate to say that his lordship had seldom heard so complete an abandonment of the case the defendants came into Court to prove. How did the matter stand? The plaintiffs described the Pielsticker process, and called evidence to prove that when the electric current was passing, as the defendants used it, it had no effect on the dissolving action of the solvent as distinguished from the depositing action. His Lordship had, during the case, said that the state of the evidence was so unsatisfactory that further experiments ought to be tried. The plaintiffs had called Lord Kelvin, who might have been right or wrong; but he prescribed his own apparatus, and the experiment carried out by him did prove that there was less gold when the current was passing than when it was not. The defendants took the apparatus away, and they gave evidence that Lord Kelvin's experiment was untrustworthy, because the solution could pass through the second carbon division. Thereupon, the plaintiffs in open Court offered that these experiments should be renewed. What happened? The defendants abandoned the electricity distinction; they were obliged to admit that they could not rely upon any distinction due to the fact that they had superadded electricity to what Mr. McArthur had patented. With regard to Rae, he asked the Court to remember that the evidence was that Rae had abandoned the cyanide of potassium, and worked by electricity alone. What was necessary in order that Rae could be used as an anticipation of the plaintiff's patent? He said, without hesitation, that sufficient directions must be found to tell people to abandon the electricity, and to rely upon the dissolving action of the cyanide of potassium.

Mr. Justice ROMER said that what would be said against the plaintiffs was this: That the general knowledge was that cyanide of potassium would dissolve gold under certain circumstances; and though there possibly might be a doubt whether you could dissolve gold in crushed ore, here was Rae saying, "You certainly can, and the use of the electric current will facilitate it."

Sir R. WEBSTER: I say the electricity is to make the solution.

Mr. Justice ROMER did not take that view, having regard to the language of the specification, and said that the defendants said that if any person had any doubt whether cyanide of potassium would dissolve the gold in the crushed ore, after reading Rae he could not have had a doubt about it.

Sir R. WEBSTER said that was the strongest thing in his favour. Rae had told people that they could have a perfect solution by the aid of electricity; he had never told people that they could get a perfect solution by the action of the chemical. What Rae said was that if you desired to get the maximum solution of gold you must have an electric current. He (Sir Richard Webster) denied that the defendants were entitled to eke that out by saying that it was previously known that cyanide of potassium had a solvent action on gold in ore. Rae told people that cyanide of potassium had a certain solvent action on gold in ore; but that, if it was desired to make it a practical solution, you must have electricity to aid it. He submitted that Rae could not be read as if the electricity was not there. He knew of no case in which in order to invalidate a patent the defendant had been allowed to rely upon that which was contrary to the directions of the alleged anticipating patent.

Mr. Justice ROMER said that this was not put against the plaintiff as anticipation directly, but on the question of anticipation generally. It was said by the defendants that if cyanide of potassium was found to dissolve gold, presumably it would dissolve gold in ore; but if there were any doubt that it could be applied usefully, Rae said that it could be usefully applied to ore, though it was better to have electricity.

Sir R. WEBSTER denied that Rae showed that, and submitted that this kind of anticipation was not sufficient to invalidate the patent. With regard to the suggestion that persons had paid £117,000 for a step which was merely the omission of a chemical from Simpson's patent, he asked the attention of the Court to the greatness of the step taken by the plaintiffs' invention. It was not until the reply that any suggestion was made that it was not a great step. In conclusion, the learned counsel said that this case was to be decided by the evidence, and he submitted that this most useful invention, which had been pirated by the defendants because it was a useful invention, was the result of experiment, research, and the bringing to bear of great skill and knowledge; that it had not been generally or specifically anticipated; and that the defendants ought to be restrained by injunction from taking that which had been proved to be a new and useful invention.

Mr. Justice ROMER reserved judgment.

Hamilton v. Vaughan-Sherrin Electrical Engineering Company (Limited).

This case, which came before Mr. Justice Stirling, raised the question as to whether a person who has, during infancy, entered into a contract to take shares in a company is, upon repudiating the contract, entitled to recover from the company money paid in respect of such shares. The defendant Company issued a prospectus, on the faith of which the plaintiff applied for shares, and paid £20 on application. On October 6, 1890, shares were allotted to her, and on the 18th she paid £40. At that time the plaintiff (a lady) was aged 18, and on November 18th following she wrote a letter to the secretary asking for repayment; and on May 19, 1892, she issued a writ; and on June 10th following the Company went into voluntary liquidation. On June 27th the liquidator removed the plaintiff's name from the register of shareholders. The action now came on upon a summons for the purpose of deciding whether the plaintiff was entitled to the return of the £60 paid by her to the Company.

The learned JUDGE, in giving judgment, said that the action was based on the ground that there had been a total failure of consideration. Then the plaintiff was an infant, and it seemed to his lordship that the true rule was to consider whether the infant had derived any advantage under the contract. In this case no dividend had been declared, and the plaintiff took no part in the Company and attended no meetings. The only advantage she got was the allotment of the shares, and the fact that for a certain period her name remained on the register. That was not an advantage within the meaning of the judgments in "Corpe v. Overton." There was here a total failure of consideration, and the plaintiff was entitled to recover.

Judgment accordingly.

Digitized by Google

The Printing Telegraph Company v. Drucker.

This was an action for calls. The plaintiffs appealed to the Master of the Rolls and Lords Justice Kay and Smith from an order of Justices Wills and Williams affirming a direction of a Master and a Judge in Chambers for a commission to Paris asked for by defendant to prove his plea of non-liability consequent on misrepresentation.

The Master of the Rolls said the defendant, in answer to an action for calls, pleaded misrepresentation; and, to prove his case, desired the evidence of people abroad who had been heard under another commission in another action, and who had, it was true, given answers to questions part of which undoubtedly related to the same issue as the defendant raised, and part not. This evidence having been given in another action, he thought there was no power to make it available in the present, and that defendant was entitled to the commission. Were it otherwise, he knew of no power in this Court to make something evidence which by law was not evidence, as the evidence in Lord Windsor's case would not be in the respondent's action.

The appeal was dismissed.

Edison-Bell Phonograph Company v. Hough.

The hearing of a motion for an interim injunction to restrain the defendant (trading as the London Phonograph Company) from infringing certain rights which the plaintiffs claim to possess in a patent of 1886 for improvements in phonographs, was concluded before Mr. Justice Stirling on Tuesday.

The Defendant having offered to pay £25 into court, his LORDSHIP said that upon that sum being paid in, and on the parties undertaking to prosecute the action without delay, he thought there ought not to be an injunction, but the defendants must keep the usual account.

The injunction was, therefore, refused.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1894 Edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK contains 1,000 closely-printed pages, and several new and useful features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d. *The 1895 edition is in active preparation.*

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," being four Lectures delivered before the Royal Institution in April-May, 1894, by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is in preparation, and will shortly be published.

"THE WORK OF HERTZ."—The lecture delivered by Dr. O. J. Lodge at the Royal Institution on June 1st is being reprinted with corrections and additions, and many illustrations, and will shortly be ready, price 2s. 6d.

"ELECTROMAGNETIC THEORY," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—This book, written by Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

TENDERS INVITED.—The Cheshunt Local Board invite tenders for the public lighting of their district by gas, oil, or otherwise. Tenders must be in not later than Monday next, the 6th inst.

——— The Vestry of St. Pancras (London) are prepared to receive tenders for the supply and laying of armoured cable mains. Specifications, &c., can be obtained at the offices of Prof. H. Robinson, 13, Victoria-street, London, S.W.; and tenders must be sent in to Mr. Albert E. Pycraft, chief clerk, Electricity and Public Lighting Department, Vestry Hall, Pancras-road, N.W., by noon of Thursday, the 16th inst. Further particulars appear in our advertisement columns.

——— The City Council of Melbourne (Victoria) invite tenders for the supply and delivery of 500,000 arc lamp carbons required in connection with the electric lighting scheme. Tenders have to be sent in by September 11th next to the Town Clerk, Melbourne.

TENDERS ACCEPTED.—The Electric Lighting Committee of the Tunbridge Wells Town Council recommend the acceptance of the tenders of Messrs. Langley and Co., of Crawley, for the erection of the central electric lighting station buildings for the sum of £2,789.

——— The West Ham Town Council have accepted the tender of the Brush Company for the electric lighting of the Public Hall and Library at Canning Town. The plant is to include duplicate engine-power and footlights for the stage; but is exclusive of buildings and foundations for the machinery, and is subject to the employment of Crossley's Otto gas-engines. The following is a list of the tenders received:—

Fanshawe and Grant...	£917	Ronald A. Scott (Ltd.)	£1,508
Henry F. Joel and Co.	1,055	Leonard G. Yate	1,535
Brush Electrical Eng. Co.	1,075	J. H. Holmes and Co.	1,536
Rayner, Smith and Co. (part)	1,127	Thames Ironworks Co. (Ltd.)	1,537
Fowler, Lancaster and Co.	1,196	Ditto	1,697
Harry South	1,215	Ditto	2,047
Fenton and Barnes...	1,225	J. G. Statter and Co. (Ltd.)	1,549
Wenham and Waters	1,230	Lund Bros. and Co.	1,551
Paterson and Cooper (part)	1,257	Stone and Co.	1,561
F. Suter and Co.	1,261	Parr and Gillies	1,576
B. Verity and Sons...	1,340	Crompton and Co. (Ltd.)	1,584
Rowland, Barnett and Co.	1,345	Brown and Co.	1,600
C. A. Hemningway (part)...	1,350	Hill, Percival and Co.	1,611
Roger Dawson, Ltd. (part)	1,369	John C. Christie (part)	1,668
Laing, Wharton and Down	1,370	Edmundsons, Ltd....	1,674
W. Mackie (part)	1,374	Marryatt and Lillywhite	1,709
Peter Jones...	1,423	New and Mayne	1,725
Vaughan and Brown	1,429	Hulett and Co. (Ltd.)	1,779
J. C. Howell, Ltd. (part)	1,439	Douglas C. Bate	1,824
British Electric Light Co.	1,448	Benham and Sons	1,876
Strode and Co.	1,487	Rashleigh, Phipps and Co.	1,888

TENDERS RECEIVED.—The following tenders have been received by the London County Council in connection with the electric lighting of the Victoria Embankment and Waterloo and Westminster Bridges:—

(1) *For the supply of engines and electrical appliances:*

Electric Construction Company (Ltd.), Wolverhampton...	£4,410
Crompton and Co. (Limited)	4,444
Greenwood and Batley (Limited), Leeds	4,565
J. G. Statter and Co. (Limited)	4,629
Paterson and Cooper	5,000
Johnson and Phillips	5,200
C. A. Parsons and Co., Newcastle	5,471
Brush Electrical Engineering Company (Limited)	5,437
T. Scott Anderson, Sheffield	5,660
W. Mackie	8,880
Laing, Wharton and Down	12,100

(2) *For the supply of boilers, &c.:*

Yates and Thom, Blackburn	£2,436
J. Watt and Co.	2,450
Babcock and Wilcox (Limited)	2,554
Maudslay, Sons and Field (Limited)	2,765
Spurr, Inman and Co. (Limited), Wakefield	3,375
Davey, Paxman and Co., Colchester (informal)	1,403

(Remainder of London.)

(3) *For the erection of generating station buildings:*

Foster and Dicksee (London)	£5,562

The consideration of the contracts has been deferred until next spring.

APPOINTMENTS.—The Electric Lighting Committee of the Hampstead Vestry have finally considered the question of the appointment of chief electrical engineer to the vestry, for which six of the candidates had been selected as being eligible. Eventually Mr. R. A. Chattock received the appointment. The salary commences at £200 per annum. Mr. Chattock is a young man with considerable experience. He has been superintending engineer at the Amberley-road Station of the Metropolitan Electric Supply Company since 1892, and was senior Gilchrist scholar at University College, London.

——— Mr. A. Grundy, late Manager and Director of Baily and Grundy, London (Limited), has been appointed electrical engineer to the Battersea Polytechnic Institute.

BANKRUPTCIES.—At a recent sitting of the London Bankruptcy Court, Arthur French St. George, of Marine-street, Bermondsey, applied to pass his examination upon accounts showing a total liability of £1,033, with a deficiency of £529. The bankrupt had previously failed in 1883 and again in 1886, and since the latter failure had been occupied in perfecting and patenting inventions. The examination was ordered to be concluded.

——— Alan Kirk, electrical engineer, was, at a recent sitting of the London Bankruptcy Court, allowed to pass his public examination on accounts showing liabilities of £328, and assets £3. The bankrupt commenced business in July, 1892, on money advanced by his father to purchase a third share in the business of medical electricians, carried on under the style of the Electro-Medical Apparatus Company, at St. Martin's-lane, London, W.C., the bankrupt's partner being Mr. H. Newman Lawrence. The business failed, and the bankrupt has since travelled for an electrical firm on commission. The examination was concluded.

OBITUARY.—The death is announced of Sir George R. Prescott, Bart., Chairman of Callender's Bitumen Telegraph and Waterproof Company, and Director of the Chelsea Electricity Supply Company.

Digitized by Google

SALE OF MACHINE TOOLS, &c.—Messrs. Wheatley Kirk announce that they have for disposal lathes, screwing, punching and shearing machines, tools, &c., for which offers are required for a prompt sale to close an estate.

PRESENTATIONS.—A few personal friends of Mr. J. Rance, jun., presented him on Monday last with a pair of binocular glasses and a pocket compass, prior to his departure to the Transvaal for Messrs. Johnson and Phillips, to erect a transmission plant for the Sheba Gold Mining Company.——On Thursday evening, last week, the staff of the Birmingham district of the National Telephone Company presented Miss Bailey, late chief operator, with a testimonial and address on the occasion of her leaving the service to be married. Miss Bailey was the first telephone operator in the district, and has been chief for more than 14 years.

THE BEAUMONT-WALLINGTON HIGH-SPEED STEAM ENGINE.—The demand for highly efficient high-speed, vertical, enclosed steam engines for electric supply stations has stimulated inventors, and has led to the introduction of a class of engine little known before the days of electric lighting. The latest of these new engines is the "Beaumont-Wallington" engine. This engine is constructed with from one to three cranks, and is arranged for simple, compound, or triple expansion, the cylinders in the two latter cases being arranged tandem fashion. The crank case is completely enclosed when the engine is working, but may be readily opened out for repairs or inspection of the interior. The steam acts only on the down stroke, and the pistons are balanced. The steam distribution is effected by a central piston valve, and is regulated by automatically varying the point of cut-off. A new and ingenious form of radial gear has been introduced for the purpose of controlling the action of the valve. An indicator diagram taken from one of these engines shows several good points in the distribution, among which full admission, quick cut-off, and free exhaust may be mentioned.

HOLIDAYS.—The Automatic Standard Screw Company give notice that their works at Halifax will be closed from the 18th to the 25th inst. inclusive.

BANK HOLIDAY POSTAL ARRANGEMENTS.—Circulars can be obtained at the principal post-offices throughout the country, giving particulars of the postal arrangements for the Bank Holiday. Special arrangements have been made with regard to express letters, and parcels for special delivery.

OUTING.—The technical staff and officials of the Electric Construction Company (Limited), of Wolverhampton, held their annual picnic at Enville on Saturday last, and by the courtesy of Countess Stamford were enabled to view the beautiful gardens on the estate.

ABERDEEN.—The Gas and Watching Committees of the Town Council are anxious to arrive at a new understanding in regard to the cost of street lighting; but the consideration of the proposal discussed at the last meeting of the committees has been postponed pending the presentation of the first year's accounts.

AFGHANISTAN.—It is stated that the present Ameer is a man imbued with progressive ideas, and that he has recently decided to introduce the electric light into Cabul. Mr. R. Jamieson Browne, electrician to the British India Steam Navigation Company at Calcutta, has just been instructed to proceed to Cabul to fit up the installation there.

BACUP.—Mr. J. N. Shoolbred, electric lighting engineer to the Borough of Bradford, has sent in a report to the Bacup Town Council giving the results of the past five years' working of the electric light supplied by the Bradford Corporation.

BATH.—The application to the Board of Trade for a Provisional Order made by the Bath Electric Lighting Company is, we understand, to be opposed by the Urban Sanitary Authority on the recommendation of their Lighting Committee. As matters at present stand, the Municipality can purchase the Company's undertaking by valuation or arbitration in four years' time, but if the Order now applied for is granted the Company will continue in possession for 21 years. It is pointed out that the Corporation are in a favourable position for obtaining motive power from the water wheels at Bathwick, and are, therefore, in a position to deal, under favourable conditions with the electric lighting question.

BIRMINGHAM.—It is proposed to make considerable extensions at the Scarlet Fever Hospital in this city, and, from a report of the Health Committee of the City Council, it would appear that a large sum is to be spent upon electric lighting at the hospital at Winson Green. The work to be done is to include a telephone installation, lighting throughout by electricity, and the provision of electric bells. The total amount to be spent on the extension is £35,900.

BRIDLINGTON.—The North Cliff has just been lighted for the first time by electricity, arc lamps being used. The lighting extends from the north end of Prince's Parade to Trinity Cut. The result has been that the promenade has become exceedingly popular in the evenings. The plant used is the same as that in use for lighting the Prince's Parade, where there is still some reserve power for future small extensions.

BRISTOL.—The Electrical Committee of the Corporation are so far satisfied with the replies to the circulars recently issued in reference to the extending of the electric lighting mains to Clifton and Tyndall's Park that they have unanimously decided to extend the mains to Clifton forthwith. The local gas company has reduced the price of gas from 2s. 10d. to 2s. 8d. per 1,000 (a saving of £12,000 per annum to consumers), and has carried forward £10,000.

CHURCH LIGHTING.—The parish church of Leeds is undergoing alteration and redecoration, and is to be lighted throughout by electricity.

DENBIGH.—The Town Council of Denbigh discussed at their last meeting the singular proposal to enter into a contract with the local gas company for the supply of gas to the public lamps for a period of five years. There is, of course, nothing remarkable in such a proposal from the gas company's point of view; but that such a scheme should be seriously discussed in face of the fact of the almost general use of the electric light by municipal bodies is noteworthy. After discussion the question was referred back to the Lighting Committee for further consideration, with an instruction from the Council to consider the best steps to be taken to secure the early introduction of the electric light into the town. One member proposed that the Council should offer a prize for the best scheme for lighting Denbigh by electricity. North Wales was favourably situated in regard to water power, and in the near future every town in North Wales would be lighted electrically.

DERBY.—The Electric Lighting Committee of the Town Council have ordered 40 new motors at a cost of about £300, and extensions of the electric lighting mains have been ordered in several additional diitricts. The Committee report that the electric lighting exhibition in May last was well patronised by the public, and that the cost to the Corporation was less than was at first anticipated. Leaving out the item of current (£45) the expenses were £76. 17s. 11d.——At the County Police Court three lads were summoned for maliciously injuring telephone wires belonging to the National Telephone Company at Breadsall. Mr. W. A. Baxter, the local manager of the Company, said that in a section of 12 miles £50 had recently been spent in repairs owing to this malicious damage. Fines of 5s. and costs were inflicted.

DUNOON.—In times past the Dunoon Town Council were satisfied with a display of gas lighting in the handsome Castle gardens under their management, but this season the Roads Committee have obtained the sanction of the Council to illuminate the gardens by electricity; and last week, in the presence of more than 3,000 spectators, the formal ceremony of turning on the light was made the occasion of a popular demonstration. Dunoon is the first Scottish watering-place to instal the electric light, and from the satisfaction given by the contractors for the work, Messrs. Walter Dixon and Co., of Glasgow, it is likely that other places of popular resort in Scotland will speedily adopt the electric light. So popular was the demonstration at Dunoon that excursion trains were run on Saturday last to carry spectators to the second illumination of the gardens.

EDINBURGH.—The terms of the proposed new lease and the scheme for the proper working of the Edinburgh tramways were under consideration at the last meeting of the Tramway Committee of the Corporation. Various suggestions were made with the view of providing a working arrangement between the lessees, Messrs. Dick, Kerr and Co. and the Edinburgh Tramways Company, and it was stated that unless the terms were agreed upon an appeal will be made to the Board of Trade to settle the points in dispute. The matter is to come up again at the next meeting of the City Council on the 28th inst. The lease now held by the Company expires in December next.

ELECTRIC LIGHTING AT THE EAST AND WEST INDIA DOCKS.—At the general meeting of the proprietors of the East and West India Docks Company, Mr. J. H. Todd, the Chairman, in the course of his remarks, said that the Company had spent nearly £12,000 in their electric light installation at the Albert Docks, and that this outlay had proved of a very satisfactory and remunerative character, the saving during the past six months reaching the large sum of £1,000. The set of electric travellers at the wood wharf had also resulted in great economy, and it was the Directors' intention to introduce more of these travellers at an early date. New boilers and engines have been put in at the Victoria Docks, with a result favourable to economy and efficiency.

EMBEZZLEMENT.—George Wilson, 29, clerk, was charged at Marlborough Police Court, before Mr. Hannay, with having embezzled sums amounting to £10, which he had received from Messrs. Nelson Dadge and Co., of Cecil-court, Charing Cross-road, on behalf of his employers, the Electrical Accessories Company, of Charing Cross-road, London, W.C. Mr. Nelson Dadge said his firm was a customer of the plaintiff Company. On May 31st he paid the prisoner 15s. 4d., and received the receipt produced. On June 25th last he also paid the prisoner £3. 13s. 8d., and received

Digitized by Google

a receipt. Mr. C. L. Schwind, Managing Director of the Electrical Accessories Company, said the firm had the books overhauled by an accountant, who had found a number of fictitious entries. On the 16th inst. the prisoner was taxed with the irregularities in the books, and acknowledged that he had appropriated the money to his own use, and agreed to make out a statement of his defalcations, which he said amounted to £16. 16s. 10d.; but further amounts of something like £80 had since been discovered. Mr. Hannay remanded the prisoner till Wednesday, when he was sentenced to six months' hard labour.

FAREHAM.—It is stated that the petition presented to the Board of Trade against the purchase by the Local Board of the undertaking of the Fareham Electric Light Company received 429 signatures, representing about one-third of the rateable value of the parish to the general district rate.

GAS MANAGERS' ASSOCIATION.—The thirty-third annual general meeting of the members of the North British Association of Gas Managers was held at Glasgow last week under the presidency of Mr. James M'Gilchrist, who, in his inaugural address, after pointing out the necessity for the gas companies keeping the price of gas at as low a figure as possible, made some references to the electric light. He said that since he last addressed them, in 1881, electric lighting had had a good trial, and were it not for its high cost it would become popular. It was, however, still the rich man's light, and, he feared, could never be anything else. Many and great improvements must be made in electrical plant before electricity could be taken seriously as a rival to gas in point of expense. The Corporation of Glasgow had spent thousands of pounds experimenting on electric street lighting, and only a few pounds experimenting with the Welsbach system of lighting by gas. Gas was being applied to new purposes every month of the year, and the consumption for purposes other than lighting continued to increase. Among the latest successful applications of the gas engine in this country was the Traction Syndicate's system of propelling street tramcars at Glasgow. The car was propelled by an 8-H.P. gas engine of the Otto type, and when charged would run for eight miles, taking heavy gradients and sharp curves with ease. The cost per mile for gas was about 1d. Horse haulage, on the other hand, was said to cost 6d. per car mile. Should the Glasgow Corporation prove these figures correct, an enormous saving would result when they propelled their cars with gas of their own manufacture.

GEELONG (VICTORIA).—As stated in our issue of the 13th ult., electric lighting matters are progressing in this district. The offer of the Crompton Electric Supply Company, of Australia, to give a complete installation for the district for the sum of £15,150, which offer was recommended for acceptance by the representatives of the Geelong Town Council and the Newton and Chilwell and Geelong West Borough Councils, has been adopted, and it now only remains for the districts concerned to give effect to the resolution.

HAMPSTEAD (LONDON, N.W.)—The Electric Lighting Committee of the Vestry have decided to purchase 50 meters, ranging from 5 to 80 amperes, at a cost of £265. 5s. Application is to be made to the London County Council to advance to the Vestry £24,400 for electric lighting purposes. An offer from Lloyd's Bank to advance money for two years at 3¼ per cent., was discussed, and the subject was adjourned to the next meeting of the Vestry in October.

HARROW.—Mr. R. E. H. Fisher, Clerk to the Harrow Local Board, sends us the following :—"Will you kindly correct a somewhat misleading statement in your issue of July 27th, where you say it was suggested to call in the services of Prof. Kennedy at a fee of 100 guineas. There is no proposition before the Board to that effect. Prof. Kennedy's name came to be mentioned in the following manner : One of the ratepayers at the meeting to which you refer had suggested that a second opinion might be taken, and one of the members of the Board asked at the meeting of the Board what Prof. Kennedy's fee would be. The Electric Lighting Committee did not report, but will probably do so at the meeting to be held on August 9th."

HOLYWELL (FLINTSHIRE).—The *County Herald*, in a recent issue, refers to the progress of electric lighting in North Wales, and to the necessity for its introduction into Flint. The occasion for its remarks was the sale of shares in the local gas company at Flint last week, where it was stated that "it was all nonsense to talk about electric light for the town ; gas was largely used for cooking, and for that purpose, as well as for lighting, there was nothing better. The electric lighting in parts of London had been discontinued." The *County Herald* thinks that the Cimmerian darkness of Flint at night will never be dispelled till electricity takes the place of gas.

HUDDERSFIELD.—The extensive installation of the electric light on the premises of the Huddersfield Industrial Society, was formally opened last week. Fourteen 2,000-c.p. arcs are used for outside lighting, and 34 1,500-c.p. arcs, and 270 16-c.p. incandescents for the interior. The generating plant consists of a tandem high-pressure compound engine by Messrs. T. Broadbent and Sons, Crompton dynamos, Babcock-Wilcox boilers, rope driven. The electrical work has been carried out by Mr. J. A. Edmondson.

KINGSTON-ON-THAMES.—By a clerical error in our last issue, the festivities in connection with the regatta held here were credited to Kingstown (Ireland). Messrs. New and Mayne inform us that the work carried out on the façade of the Town Hall building, which was brilliantly illuminated on the 25th inst., was done by them, and the illumination was repeated on the following Saturday evening at the request of the members of the Kingston-on-Thames Corporation.

LANCASTER. — The Electric Supply Committee of the Town Council have considered the question of keeping a stock of electric ovens and other cooking utensils for sale or letting out on hire. As a sign of the times this is distinctly interesting. Notwithstanding the fact that the Committee resolved not to entertain the suggestion for the present, a demonstration in cookery is to be held at the Storey Institute by Messrs. Crompton and Co., who are to provide all the apparatus, the Committee providing the room for holding the demonstration, the current, and the services of the electrical engineer. The price to be charged for current for cooking purposes is fixed at 7d. per unit. The committee, in their report, announce that they have resolved to obtain tenders for arc lamps for street lighting, and, having considered an application from Mr. A. S. Barnard, the electrical engineer, for an increase of salary, have made an increase from £120 to £156 per annum. The committee's report was adopted.

LEIPZIG.—It is stated that the Allgemeine Electricitäts Gesellschaft, of Berlin, has secured a contract for the construction of about 35 kilometres of electric tramway at Leipzig.

LIVERPOOL.—At the last meeting of the Mersey Docks and Harbour Board the Warehouse Committee recommended the establishment of a system of electric lighting at the Albert Dock warehouses, at an estimated cost of £2,850. Mr. R. Gladstone, in supporting the Committee's recommendation, said that for some time past they had been considering various methods by which the warehouses might be made more efficient and more productive of revenue. As a result of their considerations they unanimously recommended that electric lighting be adopted on all the floors except the vaults, one of the advantages claimed for the electric light being that the risk of fire was considerably minimised, and that work could be done on dark days and at night much more readily than now, when gas was used, and would generally permit of better work being done than was otherwise the case. The matter is to be again discussed at the next meeting of the Board.

MILL LIGHTING.—Crosse Hall Mill, Chorley, is being lighted throughout by electricity by Messrs. Bennett and Druce. The plant consists of a 12-kilowatt machine driven off the main mill engine. About 200 incandescents are distributed over the spinning department.

NEWCASTLE-ON-TYNE.—The dispute between the Corporation and the local gas company as to the liability of the Corporation to pay for gas lamps which, although not lighted, are not removed, came up for discussion at the last meeting of the Watch Committee, when it was stated that, having taken counsel's opinion on the subject, they had come to the conclusion that the Corporation were liable if they only extinguished, but did not remove the lamps. Another conference is to be held before a final decision is come to. The dispute is that, where the Corporation have discontinued the use of gas lamps in the immediate neighbourhood of electric lamps, the gas company insist upon the usual charge being paid for the gas lamps, and insist that they have legal powers to compel payment.

NEW GENERAL POST-OFFICE BUILDINGS (LONDON).—The extensive range of new buildings at St. Martin's-le-Grand is, during the current year, to be ready for the transfer of several of the telegraph departments. The clearing house, telegraph accounts, and telegraph message branches will be situated in the new block of buildings, which will provide accommodation for about 1,500 persons. The department's electrical staff is now engaged in fitting up the whole building for the electric light.

NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.—A party of members of this Society have visited Belgium, and in addition to the exhibition have had an opportunity of visiting the central station of the Compagnie Hydro-Electrique Anversoise in the Rue du Chantier, and at Brussels were shown over the interesting central station in that city.

PENRITH.—Messrs. Hetherington and Co. have introduced the electric light into their new premises in the Corn Market, the work having been entrusted to Messrs. Dennison, Parmiter and Barber. The installation consists of 106 incandescents and four 1,500-c.p. arcs. The result of a preliminary trial has proved very satisfactory.

PRINTING BY ELECTRICITY.—The printing machines used in the production of the *Oxford Times* are now successfully driven by

Digitized by Google

electricity from the mains of the Oxford Electric Lighting Company. The editor of the journal points with satisfaction to the results obtained, and states that electric power is preferable to gas or steam. In the machine room of the printing office it is very necessary that the power should be steady, quiet, and easily controlled, and, so far, this result appears to have been obtained wherever electric power has been used for driving printing machines.

PROVISIONAL ORDERS.—The Order promoted by the Harrow Local Board for power to supply current in the district has passed both Houses of Parliament.

REDFERN (N.S.W.).—During a discussion which took place in the Redfern City Council as to the cost of electric lamps, it was pointed out that many varying prices had been given for these lamps, and the Mayor, who was authorised at the meeting to purchase 2,500 lamps for street lighting at a cost not exceeding 5s. per lamp, was asked to communicate with the manufacturers in England to ascertain on what terms a regular supply could be secured. The Council has in the past paid as much as 8s. per lamp.

SHOREDITCH (LONDON).—The London County Council have agreed to loan the Vestry of Shoreditch the sum of £12,200 for the purchase of the site of a dust destructor and electric lighting station.

ST. HELEN'S.—The Corporation have appointed Mr. Robert Hammond to draw up a report and submit estimate of cost in connection with their electric lighting scheme.

SUNDERLAND.—The Corporation have decided to fix the price to be charged to consumers of electric current at 6d. per unit.

SUTTON (SURREY).—The Provisional Order obtained by the Local Board expires in June next, and the Clerk was instructed at the last meeting to communicate with the Board of Trade in order that sanction should not be given to any company or individual in the promotion of any scheme for lighting the town by electricity without first obtaining the sanction of the Local Board.

THEATRE LIGHTING.—Mr. Wilson Barrett has introduced the electric light at the Royal Court Theatre, Wigan, where the auditorium, which has been redecorated and reventilated, is to be installed throughout with the electric light.

TOWN AND COUNTRY HOUSE LIGHTING.—Eastwell Park has been taken by Lord Rosebery as a Kentish residence. Extensive alterations and improvements are being effected at the mansion, and the electric light is to be installed throughout.——Fawley Court, Henley-on-Thames, the residence of Mr. W. D. Mackenzie, and also the town residence of the same gentleman at 35, Park-street, W., is being fitted for the electric light by Messrs. Rashleigh Phipps and Co., as is also the town house of Mr. Anderson Critchett, the celebrated oculist, in Harley-street, W.

TUNBRIDGE WELLS.—The Local Government Board have given their sanction to the Town Council for borrowing £13,000 for electric lighting purposes, to be repaid in 25 years.

WEST HAM.—The Provisional Order obtained by the Town Council expires this year, and, on the application of the Council, the Board of Trade have agreed to consider the Order as in force for a further period of twelve months, at the same time intimating that the Board has no power to extend the time of the Order.

WEST HARTLEPOOL.—Mr. J. W. Brown, borough engineer and surveyor, has just issued his report for the year ended March 25th last. Amongst the points dealt with in the report is the sanction given by the Town Council to the local tramway company for running the tramcars by electricity on the overhead system, and the obtaining of a Provisional Order for supplying the district with electric light and power by the Corporation.

WHITECHAPEL.—A special meeting of the Lighting Committee of the Board of Works has been held this week for the purpose of considering a report regarding the lighting of the district by electricity.

WINCHESTER.—The General Purposes Joint Committee of the Town Council have, after a long discussion, decided to recommend the Council to apply for a Provisional Order to light the city by electricity. Application will also be made to the Local Government Board for power to borrow about £20,000 for the purposes of the electric lighting scheme.

WOKING.—Messrs. New and Mayne have secured the contract for lighting the streets of Woking by electricity. 25-c.p. incandescents are to be used, the first instalment consisting of 48 single-light and 13 double-light posts.

WOLVERHAMPTON.—Mr. F. Harman Lewis, borough electrical engineer, has issued a circular dealing with the advantages of electric light over gas, and calling attention to the fact that the central electric lighting station will be completed and in working order in September. The circular points out that the electric light is healthier, cooler, safer, and cleaner than any other artificial light, and when used judiciously, and with all advantages taken into account, is as cheap as gas. The Corporation charge for electric energy is fixed at 6d. per unit.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

July 21, 1894.

14,069. CARL S. ENGLISH. London. Improvements in electrical governors for water-wheels. (Date applied for under Patents, &c., Act., 1883, Sec. 103, December 23, 1893, being date of application in U.S.A.)*

14,080. GEORGE FREDERICK REDFERN. London. Improvements in incandescent electric lamps. (Carl Schwabe, Germany.)

July 23, 1894.

14,113. ALFRED GEORGE COOPER. Lewisham. Improvements in electric energy and power-recording meters.

14,123. WILLIAM PAUL THEERMAN and G. C. ELLIOTT. Manchester. Improved method of fixing electric bells and telepones.

14,156. O. W. KETCHUM. London. Improvements in or connected with electric waggons.

July 24, 1894.

14,202. H. D. FITZ-PATRICK. Glasgow. Improvements in signalling by electric lamps.

14,240. WALTER WILKE. London. A new or improved electrical apparatus for calling or waking persons in different rooms at different determined times.*

14,246. CHAS. F. SCOTT. London. An improved system of electrical distribution by alternating currents. (Date applied for under Patents, &c., Act., 1883, Sec. 103, February 26th, 1894, being date of application in U.S.A.)

July 25, 1894.

14,290. G. BINSWANGER. London. Improvements in electrical lamp-holders and similar electrical fittings.*

14,303. CARL RAAB. Liverpool. An improved electricity motor meter.

14,312. JAMES THORNHILL ASHTON. London. Improvements in automatic switch devices for electric currents.

14,320. G. A. KINGDON. London. Improvements in dynamo electric machines and electromotors.

14,327. A. F. B. GOMESS. London. Improvements in the manufacture of aluminium and aluminium alloys, and the electro-deposition of the same.

July 26, 1894.

14,340. H. C. RISBOROUGH SHARMAN. Merton. An improved electro-massage roller appliance.

14,371. G. R. NEILSON and A. C. BROWN. London. Improvements in fire-alarm telegraphs.

14,394. H. G. DALE. London. Improvements in induction coil apparatus for electro-medical and other purposes.

July 27, 1894.

14,445. JAMES Y. JOHNSON. London. Improvements in or connected with electric railways and vehicles. (Malone Wheless, U.S.A.)*

14,455. E. TEMPLETON and H. P. SCHISCHKAR. London. An improvement in lightship connections for submarine cables.

14,488. J. JEFFREY and J. LEA. London. Improvements in or connected with electric arc lamps.

July 28, 1894.

14,492. A. G. ADAMSON. Glasgow. Improvements in the chamber or reflector for carrying the lamps used in photography by electric light.

14,493. A. G. ADAMSON. Glasgow. Improvements in apparatus for the use of electric light for photographic purposes.

14,509. H. V. KEESON. London. Improvements in electric current regulators.

14,511. R. HARTLEY and G. B. COCKS. Rochdale. An improvement in electric stop motion drawing frames.

14,518. A. WHALLEY. Helsby. Improvements in telephone switchboard apparatus.

14,533. J. A. FLEMING. London. Improvements in apparatus for transforming electric currents.

14,536. CHARLES F. PARKINSON and W. GATWOOD. Manchester. Improvements in apparatus for heating and welding by electricity.

14,545. THOMAS PARKER (LIMITED) and THOMAS PARKER. London. Improvements in the construction of dynamo-electric machines and electromotors.

14,546. SALLY DAVID. London. Electric contact by weight.

14,551. DAVID YOUNG. London. Improvements relating to the transmission of signals through submarine cables and other telegraph and telephone lines and to apparatus therefor. (John Mabry McMahon, U.S.A.)

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price of 8d. each.

1893.

12,971. DAHL. Alternating current motors.
13,111. PEASE. Dynamos and electric motors.
13,133. MCLEAN. Electromagnetic switch.
14,664. KINGDON. Electromotors.
14,953. SHARP. Incandescent electric lamps.
16,017. GIBBS, H. W. and G. J. Electrically-actuated machine tools.
16,597. GEUTZSCH. Inspissated oil for electrical insulating purposes.
16,857. GEUTZSCH. Electrical insulating material.
17,310. SIEMENS BROS. AND CO., LIMITED (Siemens and Halske). Electric railways.

1894.

367. LONGSDORE (Hewett). Galvanic batteries
8,638. PITT (Blondel and others). Dynamo-electric machines.
9,215. DAVIS. Circuit control for electric machines.
10,186. NASHOLD. Cleats for electric wires.
10,590. EDISON and SWAN (United Electric Light Company, Limited, and Proctor). Switch and holder for electric glow lamps.
10,594. FRANK. Telephones.
10,660. GOLBZ (Neumann). Incandescent electric lamps.
10,853. JOHNSON (Société l'Accumulateur Fulmen). Electric accumulators.

COMPANIES' MEETINGS AND REPORTS.

Anglo-American Telegraph Company (Limited).

The ordinary general half-yearly meeting of the proprietors of this Company was held at the City Terminus Hotel, Cannon-street, on the 27th ult., under the presidency of the Most Hon. the Marquis of Tweeddale.

The SECRETARY (Mr. T. H. Wells) read the notice convening the meeting and the minutes of the last meeting. The report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, the traffic receipts have proved extremely disappointing. They amounted for the past half-year to £130,094, showing a decrease of £16,791. Although very disappointing, I cannot suppose that this decrease has surprised any one who has any knowledge of the condition of commerce both in this country and the United States. That an improvement, sooner or later, may be hoped for and expected is, no doubt, the case, but so long as the tariff question in the United States remains unsettled, there is little or no prospect of any change. When, however, that matter is settled, we may look forward to a very substantial increase in our traffic receipts. The steamship "Minia" has happily come to our rescue financially, and earned £4,050 more than was earned this time last year; and again, our expenses have been reduced in a very substantial manner, the saving amounting to no less than £4,466. The principal items of this reduction are salaries and wages, which are £1,721 less, and in maintenance of our lines there has been a saving of £1,123. I hope the shareholders will observe that we have endeavoured to fulfil our promise to reduce expenses as far as possible, while at the same time maintaining the efficiency of our system. The net result is that after placing £12,000 to reserve we are able to recommend a dividend on the Ordinary Stock for the second quarter of the half-year of 10s. per cent. and of 1 per cent. on the Preferred Stock, carrying forward £1,173, or £670 more than last year. The condition of the cables is naturally a matter of great importance, and I am happy to be able to inform you that the 1874 cable has been repaired at last. You will remember that last year, owing to the extraordinary prevalence of bad weather the whole time the Telegraph Construction Company's ship was on the spot, we were unable to effect the repair; but this year Capt. Trott has accomplished the task most successfully. You all know that he is one of the most efficient telegraph captains in any service, and I am sure you will all congratulate him on the success of his efforts in restoring the 1874 cable. I am also happy to be able to add that our new cable has been laid successfully by the Telegraph Construction Company. The last splice was made a very short time ago—I believe within a few minutes; but, at any rate, it has been laid, and with the usual skill and success of the Telegraph Construction Company. The other two cables are in good working order, so that we have four cables across the Atlantic now in first-class order, and they are all duplexed. The fifth cable—the French cable—we have not attempted to repair this year. Having regard to the advanced state of the season, and the time the "Minia" would take in going out, I do not think there is any probability of that repair being undertaken this year. The expenses of the new cable and of the repair of the 1874 cable have made serious inroads into our renewal fund. The repairs last half-year cost £26,000, and this half-year they will cost about £20,000 more. The fund will, therefore, be reduced to a figure of something like £530,000. I need hardly repeat what I said at the last meeting, that the amount we propose to set apart to this fund—£12,000 each half-year and the interest of the fund—is a minimum figure. We should be only too glad to be able to add a larger sum, but in view of the fact that our cables are in such good order, and that we have a new one, which may be justly considered, for a few years at least, as part of our reserve, we believe that we shall be able to go on with that small sum added to our reserve—at any rate, for some time. We have just received a telegram from Valentia stating in regard to the new cable that the signallings are good. No doubt you have heard with considerable interest that judgment has at length been given in our favour in the proceedings with regard to the Pouyer-Quertier cable. The judgment proves, at any rate, that our contention was a correct one, that the French Company committed a serious breach of their agreement. So far that is established. Whether the result of that decision will be attended with any great financial benefit to the pool companies is doubtful, but it would be impossible to express an opinion as to what view the experts, who were to assess the damages, will take, and I shall not hazard one. We, however, strongly object to that part of the decision which limits the period of damages from December, 1886, to May, 1891, and we are considering whether it would not be wise and proper to appeal with respect to that part of the judgment. The opinion of the most eminent counsel in Paris is being taken at this moment, and upon their recommendation will depend the action of the pool companies. Gentlemen, I have no doubt that you have heard with some dismay of the possibility of one or two more cables being laid in the Atlantic. One is said to be contemplated by the French people and the other by the German Government. As I have often pointed out, the Atlantic is free to anyone, and there is no security against fresh cables being laid if only people are willing to subscribe sufficient money to lay them. So far as the French intentions are concerned we have no information whatever of a reliable character, but the case is different with respect to Germany, because we have reason to believe that the German Government does contemplate giving a concession for a new cable from Germany to America. It is not surprising either that the French people or the German Government should desire to have greater facilities than they possess at present; and, therefore, we need not wonder if the French people should at some time or other lay another cable, or if Germany should give a concession for a second means of communication with the United States. I believe the concession contains a subsidy—a grant of money to the concessionaire, and I believe that a cable may be expected to be laid, but certainly not sooner than 1897 or, probably, 1900, so we have a considerable time yet before any cable of that kind will be put down. As far as I aware, no concession has yet been granted. I said it was contemplated, and that is all I know about it in that respect. I think, however, you will agree with me that if a concession is granted by the German Government we may hope that it will fall into the hands of friends rather than of enemies—in the hands of those who, having large interests in the pool companies, both directly and indirectly, have strong inducements to deal more tenderly and in a more friendly spirit with any new company formed for the purpose of carrying out this cable than would be the case if the concession fell into the hands of enemies—that is to say, of hostile competitors. I do not think I need trouble you with many other remarks. There is, perhaps, one item in the general balance-sheet which requires explanation. Under the head of sundry creditors you will observe that there is a figure of £65,000 more entered than in the year 1893. This is due to the fact that £60,000 is owing to the Telegraph Construction Company for cable purchased for stock, repairs, &c. With your permission I now beg to propose—

"*That the report of the Directors and accompanying statement of accounts to June 30th, 1894, submitted to this meeting, be, and the same are hereby, received and adopted.*"

The DEPUTY CHAIRMAN (Mr. Francis A. Bevan) seconded the motion.

The CHAIRMAN expressed his readiness to hear any remarks that any shareholders might wish to make.

Mr. GOODSALL inquired what amount of cable was expended by the steamship "Minia" in effecting the last repair, and was it all used?

The CHAIRMAN: About 220 miles, and it was all used.

Mr. GOODSALL asked whether the condition of the 1874 cable had been reported. As far as he could make out, it had unfortunately been laid with too little slack.

The CHAIRMAN: I shall be in a position to give a much more satisfactory answer to that question when we get our information from Captain Trott; but I believe the cable is in very fair condition. He then put the resolution, and declared it carried unanimously. He added that that closed the business of the meeting, and he only hoped that they would have a better report to submit on another occasion.

Mr. JOHN NEWTON proposed a vote of thanks to the Chairman and Directors, remarking that their labours of late had undoubtedly been more arduous than at any previous time.

The motion was seconded and agreed to.

The CHAIRMAN, in returning thanks, assured them that the Directors were doing their best in the proprietors' interests, and very considerable labour was thus involved.

The meeting then separated.

Chili Telephone Company (Limited).

The annual general meeting of this Company was held yesterday at Winchester House, Mr. Thomas Greenwood (Chairman) presiding.

The SECRETARY (Mr. Edmund Petley) read the notice convening the meeting.

The CHAIRMAN: Gentlemen, I apprehend you will not deem it to be a profitable occupation of your time to take a discursive view of the accounts and report. If I may take that for granted, and if any shareholder requiring further information will be good enough to put his question, I will, without any detailed comment on the report and accounts, ask you to adopt them. But I think it may be agreeable to you that I should say a word or two about the position and prospects of the Company. There can be no doubt that the year, through which we have

Digitized by Google

lately passed, has been the worst that the Company has seen, and I think I may fairly add it is the worst the Company is likely to see. There are three things requisite for the complete success of the undertaking. The first is doubtful, the second is probable, and the third cannot be estimated, being beyond the control of the Board. The first is as to the working expenses. It is only fair to say, on behalf of the officers on the other side and the Board, that from the outset every effort has been made to bring them down to as low a figure as possible. Every movement in that direction, however, has been practically cancelled by the reduction in the value of the dollar, so that, while endeavouring to save money in this direction, expenses which have been imperative have grown in amount, because, the salaries being payable in gold on the other side, we have to give away a greater number of dollars for the same services than we did when the dollar was worth more. At the same time it is not impossible that some further reduction will be made. The Board has a scheme before it with a view of making a part of the remuneration of our officers dependent upon the profits. That is a very desirable thing to do in any circumstances, and the effect of it will be that in bad times we shall have to pay less, while in good times we shall have, of course, to pay more. I think you will appreciate our object, and, I may add, that when we come to deal with the matter we shall do so in a generous spirit towards those on the other side, having due regard to the interest of the shareholders. The second point, which is probable, is the increase of our receipts. The Company have waited for years for a cash dividend, and had hoped for a rise in the exchange. Unfortunately, instead of rising, it had gone lower and lower year after year until it had touched the low figure of 10½d. per dollar. The Board, in these circumstances, had felt it necessary to increase the rates to their subscribers. We were very anxious to avoid doing so as long as possible. While our instructions were on the way to the other side the Manager there appeared to have taken the same view as ourselves, as he appeared to have issued a circular to the subscribers to the same effect practically as our own. There is no doubt that an increase of traffic may be expected, although the number of subscribers may be diminished, and I am pleased to see that during the three months which have elapsed since March 31st we have had an increase every month from our subscribers. In the first month, April, the receipts showed an increase of $1,153, in May $2,600, and in June $5,555, so that our income to the end of June was $515,000, against $505,000 to March 31st. The third item I wish to speak upon is the rate of exchange. I hold in my hand a diagram which has been sent over by the General Manager. It is a most interesting one, and there are in the centre 47 columns, representing the months of the years during which the Company has been in existence. On one side we have in a black line, starting at the left-hand corner, at the bottom, the revenue of the Company, gradually rising from $225,357 to $505,866. On the other hand the rate of exchange is depicted in a red line, commencing at the top left-hand column and ending at the bottom right-hand column, showing that we had for our dollars 26d. at the commencement of our working and that we left off at 13d., or just about half. That in itself is a complete explanation of how it is we have been so long without a dividend. At the same time I think there is a fair prospect of an improvement. You may ask what ground there is for that hope. The most knowing gentlemen we have connected with financial matters in the City have been wrong again and again, and it appears to be a difficult thing for anyone to come to a right conclusion. However, there are straws which show the way the wind is blowing. We find from the reports lately published by the Government of Chili that their position is very much better than it was, and that the amount of sterling money they have in hand ready for the redemption of currency amounts to millions. Our last advices from the other side were to the effect that the new Congress, which commenced its sittings on June 1st, had indicated a very large amount of talent, and a determination to work together rather than in a partisan spirit, with the object of doing the best they can for the nation as a whole. If the promises of the Government are fulfilled within two years we shall see our dollars worth 22d.—double what it is now—and if that be so the prospects of the Company will be very greatly improved. Indeed, any one of the three things I have mentioned will make a material difference in the aspect of affairs; but if this particular improvement takes place we may hope at an early date for dividends in cash. I now beg to move—

"*That the report of the Directors, with the statement of accounts to March 31, 1894, now presented to this meeting, be approved and adopted.*"

Hon. F. ERNEST ALLSOPP seconded the resolution, which was passed.

Mr. DEY then proposed—

"*That Mr. Thomas A. Welton be and he is hereby re-elected auditor of the Company.*"

Mr. BONNER seconded, and it was agreed to unanimously.

The CHAIRMAN: You will have noticed, gentlemen, in the report a reference to the retirement of Colonel Jackson. He was seriously ill at the time that it took place, but I am very pleased to say he is very much better now. By absenting himself from London, and residing in a more bracing atmosphere, he hopes to recover a large portion of his former strength. I thought the intelligence would be agreeable to you. The Board were very sorry to lose Colonel Jackson's services. He was a man of large commercial ability, and his knowledge of the telephone business was great. We considered Colonel Jackson an acquisition to the Board, and we regret his resignation very much. We may hope yet to see him again, and, if so, it will be announced in the usual way.

Mr. HENDERSON moved a vote of thanks to the Chairman and the Board, and in doing so said the shareholders felt, he believed, that although the report was not as satisfactory as they could wish, yet he firmly believed the Board had done their very best.

Mr. BAILLIE seconded the motion, which was carried.

The CHAIRMAN having acknowledged the vote of thanks, the proceedings terminated.

City and South London Railway Company.

The half-yearly ordinary general meeting of this Company was held at Winchester House on Wednesday, Mr. Charles Grey Mott presiding.

The SECRETARY (Mr. W. F. Knight) having read the notice convening the meeting,

The CHAIRMAN said: During the past half-year we have carried passengers numbering 236,493 more than in the corresponding period of last year, and our season ticket holders have increased by 49. This considerable increase of passengers has been carried with our usual perfect safety, and almost absolute punctuality. We have been able to get this increase in spite of the fact that during the first three months of the year the Oval remained closed for football matches, which undoubtedly deprived us of a considerable amount of traffic we should otherwise have had. But still, looking at the whole result of the half-year's working, I think you will agree with me that it is a fairly satisfactory one. We have now got this railway, in all its main details, into thorough working order, and of late your Directors have turned their attention to the question of how far they can, in the smaller details, improve the working of the line, so as to make it more convenient and more attractive to the travelling public. With that end in view we have improved very largely the station at King William-street, on the surfaces. Anyone who visits that station now, and compares it with what it was before will see that it presents a very different aspect from what it did in former days. I am happy to think that our expenditure at King William-street station is gradually likely, not only to be remunerative as the consequence of making the line more attractive, but also on account of the left luggage office, and other conveniences we have provided. The left luggage office, I think, will be of great service to our passengers as well as to the general public, because it is open and available to all persons either crossing or travelling in the vicinity of London Bridge. As this fact gets more widely known I believe it will be largely used, and bring us in a considerable revenue. We have also been trying to improve the trains, and we have now a new train on, which runs easier and with less noise, while the carriages themselves are of a much brighter and better description in many ways. As you will observe by the report, we have been considering carefully the question as to whether it would be possible to do away with the existing locomotives by substituting motors on the train itself. This, I may tell you, is the idea we started with originally, but we adopted the separate locomotives in deference to the views of the Board of Trade, and for other special and weighty reasons at the time. We have, however, now got this line into such working order that we think it may be possible to revert to our original intention of putting motors on the carriages instead of having separate locomotives. This would give us the necessary room at King William-street station to add to the trains another coach. Unfortunately we do not yet know whether we shall be able to carry our idea out. We are making experiments, but the difficulties arising from the smallness of the tunnels, and other matters, render it at present somewhat dubious whether the proposal will be practicable. I believe we shall find means of effecting the improvement, and, if so, as I have already remarked, we shall be able to accommodate a larger number of passengers by each train. Turning now to the accounts, you will notice, as regards the capital account, that we have paid off £8,200 of our Five per Cent. Terminable Mortgage Debenture Bonds, and re-issued them as Debenture Stock or Preference shares. We have received on capital account during the half-year £33,100—£2,000 from the issue of Preference shares and £31,100 from Debenture Stock, making in all £33,100. We have received in premiums on shares and debenture stock £2,580, making the total amount received £35,680. Out of this we have paid £21,000 off the loan I told you of at the last meeting; £8,200 have been applied, as I have mentioned, to the paying off of Terminable Mortgage Debenture Bonds; and we have expended on capital account £3,765. We have, further, reduced our general outstanding accounts by £1,440, which accounts for a total of £34,405 out of the £35,680 received. The small balance remaining has gone to increase the balance at our bankers and other accounts. The loan that I spoke of was originally £22,000, of which we have paid £21,000 according to these accounts, but I may add that the remaining £1,000 has been paid since these accounts were made up, so that our liabilities are now discharged, and we are free to consider the future. As regards the revenue account, the receipts from passengers show an increase of £1,106, parcels £16, transfer fees, £7, and sundry receipts £18. There is a decrease in the rents of £12, leaving a net increase of £1,135. On the other side of the account you will find that the expenditure on maintenance of way shows an increase of £110, and the locomotive department an increase of £17. There has been a decrease in carriage repairs of £89, in traffic expenses of £45, in general charges of £19, in passenger duty of £19, in law charges of £38, and in compensation of £17. But there has unfortunately been an increase of £124 in rates and taxes, which leaves us, notwithstanding the various decreases I have mentioned, with a net increase in the expenses of £26, reducing the sum of £1,135 to £1,109. After paying 5 per cent. on the Preference shares it allows us to pay 1 per cent. on the Ordinary stock, and enables us to carry forward £1,335, against £898 last year. The total working expenses for the half-year are now reduced to 61·7, against 64·61 at this time last year. If you take away all the expenses connected with the lifts, which, as I have said on previous occasions, do not properly belong to the working of a railway, it reduces our percentage of working expenses to about 52 per cent., which is lower considerably than that of many of the large railways in England. Of course, that percentage of working expenses I hope to see largely reduced in the future; but it all depends upon the increase of our traffic. It has so far gone steadily down from a very much higher figure. The receipts per train mile have been 2s. 1½d., the same as in the corresponding period of last year, because we have run an

Digitized by Google

increased mileage. The receipts per passenger work out at 1·62d., practically the same as last year, when it was 1·61d. The locomotive expenses per train mile have been 6·21d. against 6·48d. at this time last year. Deducting from these figures the cost of the carriage of coal, which is not paid for by other companies, our locomotive expenses are reduced, in comparison with them, to about 5d. per train mile. We have run during the half-year 72,179 trains, which is no inconsiderable number. I think that, as a whole, although our dividend is not as large as we should like to see it, we are making steady, if not very rapid, progress. I am afraid I cannot hold out to you any prospect of more rapid advancement as the line now stands, because, as you know, our appliances are very limited, and until some extension of the line takes place I fear we must be content with a steady and somewhat slow movement upwards; but the Board are doing their best to accelerate that movement with the materials that we possess. With these remarks, I beg to move—

"*That the report and statement of accounts for the half-year ended June 30, 1894, now presented to the meeting, be received and adopted.*"

Mr. SAMPSON HANBURY seconded the motion.

Mr. DRAKE said they were all pleased with the increase, small though it might be, in the dividend. It had unquestionably been demonstrated that electricity as a motive power was a practical thing, which was a great point. It had also been demonstrated that their line was a wonderful convenience to the enormous population of South London, through which it ran. The remaining thing they wanted demonstrated—and he was sure the Board were devoting themselves carefully, vigilantly, and perseveringly to the point—was that the line should also yield a fair return to the shareholders who had invested their money in the undertaking. They had an excellent Board and an efficient staff, capable, he believed, of managing a line three or four times its present length. They were now throttled at King William-street, and he hoped that before long the Directors would be able to find some solution for dealing with the growing traffic on the line.

Mr. SAMUEL GURNEY SHEPPARD, speaking as one who had as large, or nearly as large, an interest in the Company as any individual, advocated the extension of the line as far as Moorgate-street.

Mr. COURT, who said he represented shareholders having £100,000 in the Company, alleged that the expenses of management were too heavy, and gave notice that at the next meeting he should move a resolution for reducing the Directors' fees to £750 per annum.

Mr. MIDDLETON contended that unnecessary delay had taken place in the experiments to find out whether motors in the carriages could be substituted for the separate locomotives, and added that until the shareholders received 2 per cent. dividend he would oppose any extension.

The CHAIRMAN, in reply, said: I am afraid it is hopeless to try and satisfy Mr. Middleton. The larger the dividend the more does he say we have mismanaged the affairs of the Company. I think it is unfortunate he is not better acquainted with the working of a railway of this kind. If he were he would appreciate the difficulties which beset us, and the extreme amount of care and the constant attention which is required to carry it on in the way it has been. He deals with it entirely from an outside point of view, and says we should do this and the other without at all knowing the obstacles in the way. He referred to the motor question as if it was something he had suggested, whereas it is the very thing of all others dearest to my heart from the beginning. The whole plans were arranged for having motors on the carriages, and they were only altered at the last moment in deference to the Board of Trade. I cannot control the Board of Trade. If Mr. Middleton can, let him do so. I venture to say we have lost no time in the matter. As I have told you, it is a very difficult thing, and it is very doubtful if we shall, after all, be able to carry out our idea. So anxious are we that we have not been satisfied in giving the necessary orders to carry out the experiments to one firm, but we have given them to two, so as to expedite the matter as much as possible. I can only say that the remarks of Mr. Middleton are not encouraging to the Directors after the labour and trouble they have given to the Company's affairs. As regards the question of extensions, we have not brought that before you. I told you we should not until we had a plan we could thoroughly recommend to you. So far from Mr. Middleton's idea, that you are going to suffer in your dividends through it, being correct, I may say that, as far as we can see—and we have most careful figures before us, that can hardly go astray to any large extent—the completion of the line to Moorgate-street, after paying every possible preference charge that can be, will result in the increase of your dividend almost immediately to 5 per cent. I thank Mr. Drake for his observations, and I was glad to hear the views of Mr. Sheppard, who represents, perhaps, as large an amount of capital as anyone in this room. In view of what he has said, we shall give this question of the extension still more careful consideration. I do not suppose Mr. Middleton will support any scheme for that purpose, because he has always consistently been opposed to any extension. I will merely thank those gentlemen who have spoken kindly of the way in which we have managed the Company. It is an encouragement to us, and will stimulate us, if possible, to do more in the interests of the shareholders.

The motion was then adopted.

The CHAIRMAN then moved—

"*That the full dividend of 5 per cent. per annum be paid on the Perpetual Preference shares for the half-year ended June 30th, 1894.*"

Mr. EDWIN TATE seconded the motion, which was agreed to.

The CHAIRMAN next moved:—

"*That a dividend at the rate of 1 per cent. per annum be paid on the Consolidated Ordinary Stock for the half-year ended June 30, 1894.*"

Mr. GREATHEAD seconded the motion, which was carried.

On the proposition of Mr. COURT, seconded by Mr. DRAKE, a vote of thanks was passed to the Chairman and the other Directors.

The CHAIRMAN having acknowledged the vote, the proceedings terminated.

Globe Telegraph and Trust Company (Limited).

The twenty-first ordinary general meeting of this Company was held on the 27th ult., at Winchester House, Old Broad-street, under the presidency of Sir John Pender, G.C.M.G., M.P.

The SECRETARY (Mr. Sidney Collett) having read the notice convening the meeting and the minutes of the last general meeting, which were confirmed, the report of the Directors was taken as read.

The CHAIRMAN: Before asking you to approve the report, I will, as usual, go over some of the details of last year's working, and give you such information as I think may interest you. The receipts for the year ended the 18th inst., after paying all expenses, amounted to £185,057, as against £188,931 in the previous year, or a decrease of £3,874. This decrease is due principally to the reduced dividends which we have received from the Anglo-American Telegraph Company, in which, as you know, we have a very large interest. The object, however, of the Globe Company was, and still is, to equalise the dividends paid by the various telegraph companies in which we hold investments, and this object to a very large extent has been attained; because, while we have smaller returns from the Anglo Company, on the other hand the Telegraph Construction and Maintenance Company have given us a larger return than we had from them last year, so that we are able to recommend to-day the payment of a dividend on the Ordinary shares of 4½ per cent. for the year, against 4⅝ per cent. in the previous year. But this decrease is by no means a large one, and I may add that the dividend we are paying this year is still above the average, and that taking our Preference and Ordinary shares in like quantities they show a return of £5. 5s. per cent. Of course, gentlemen, we cannot pass through such hard times as have been existing not only in this country, but also, I may say, in every part of the world, without being affected. The decline in our dividend is, however, small and incidental, and I think that in view of the times we have been passing through we ought to congratulate ourselves that the dividend is not worse than it is. It is only ⅛ per cent. less, although every ⅛ per cent. makes up. I will, as usual, give you some information in running over the various figures which show fluctuations compared with last year's receipts. The Anglo-American Telegraph Company has paid us £4,207 less than we received from them last year, but this reduction needs a little explanation. The dividends we received last year were increased by the fact that the interest on their investments, instead of being placed to reserve fund, as formerly, were applied to the dividend, which was consequently increased by that amount; while this year not only has this interest not been distributed in dividend, but in accordance with the arrangement made at the time in connection with the laying of their new cable, which had become a necessity, certain moneys, which would otherwise have been distributed in dividends, have been placed to the reserve fund, with a view of building up that fund as soon as possible. We have also received £994 less from the Direct United States Company than the amount they paid us last year; but the remarks I have just addressed to you in reference to the stagnation in business between America and here refer to this Company in the same way as they do to the Anglo Company. However, the return this year on our investment in the Direct Company is £5. 5s. 5d. per cent. You will also have noticed that the accounts show that we received from the Submarine Cables Trust last year £1,083 more than we have received from them this year; but this difference, I may say, gentlemen, is more apparent than real, the larger dividend in the previous year being due to the fact that the Submarine Cables Trust paid the balance of the April, 1892, coupon at the commencement of our financial year, which ended July, 1893, and this amounted to £1,098, which you will at once see explains this difference. The coupons on those certificates are fixed at the rate of 6 per cent.; but for some years past they have been a little behind in their payments, and this is why the amounts they pay in one year may not exactly correspond with the amounts they pay in any other given year. With regard to the Telegraph Construction and Maintenance Company, you will remember that last year they paid us at the rate of 15 per cent., instead of, as formerly, 20 per cent., and you will also remember, gentlemen, that when I addressed you at our annual meeting last year I did not hold out much hope of a return to the high rate of 20 per cent., at least for some little time. Happily, however, it has proved otherwise, and that Company has once more reverted to its 20 per cent. dividend. This is very satisfactory to us, being large shareholders in that Company, as it means an increase in our receipts of £2,188, and we can only hope that this handsome return will be maintained. The return for this year on our investment in that Company is £6. 13s. per cent. You will have observed from the report that the Direct Spanish Company's Six per Cent. Debentures, which were held entirely by this Company, amounting to £62,000, matured on May 1st last and were paid off; £16,989 of this amount has been reinvested as follows: 300 shares in the Western Union Telegraph Company, 250 shares in the American Cable Company, 22 certificates in the Submarine Cables Trust, 354 Ordinary shares in the Direct Spanish Telegraph Company, 346 Preference shares in the Direct Spanish Telegraph Company, and the remainder will be reinvested (I may say it is already reinvested temporarily) as soon as suitable investments can be found by us. You are aware of the difficulty of getting suitable investments at the present moment. We have money in the bank, and cannot get more than 1 per cent. for it, and we are therefore obliged to fall back upon Consols for investments, and there is not a very large return from that. However, rather than leave the money unemployed, or only earning 1 per cent. at the bank, we have invested it temporarily in Egyptian Three per Cent. Guaranteed Loan and in Two and Three-Quarter per Cent. Consols. These are, at all events, safe, and will not run away from us. They are well guaranteed, and although the rate is not a high one, still we can keep the money invested in this way until we find something more in accordance with our views as to investments. The returns on the investments in other companies are practically the same as they were last year, and there-

Digitized by Google

fore call for no special remark; but it is satisfactory to note that from most of the companies in which we hold important investments we get very good returns in the way of dividends. I may mention the companies in question. From the Brazilian Submarine Company we get £6. 10s. per cent., from the Eastern Telegraph Company £6. 7s. 2d., from the Eastern Extension Company £6. 16s. 5d. per cent., from the Indo-European Company £11. 3s. 8d. per cent., from the London Platino-Brazilian Company £5. 16s. 6d. per cent., and from the Western Union Company £6s. 5s. 6d. per cent. Besides these investments we have the Direct United States Company, which yields us £5. 5s. 5d. per cent., and the Telegraph Construction Company, £6. 13s. per cent. With respect to the West African Company, I should just like to mention that, while we are not receiving any dividend from them this year, the Directors of that Company have taken every possible precaution to obviate the necessity of those heavy expenses which have had to be incurred on account of the frequent interruptions to their cables. In addition to removing the cable from its former position, as I reported to you last year they had decided to do, a small repairing vessel, specially adapted for work in those waters, has been equipped and sent out to the coast with the view of repairing any breaks which may occur with as little delay and at as small a cost as possible. This vessel has been equipped and sent out to the spot, and is at the present moment doing work continuously. I therefore hope that when I stand before you next year, if I am spared to do so, I may be able to report that we have received some return on our money invested in that company. It may be possible also for us to get some return on our West Coast of America shares now that the Transandine line is completed. As you are aware, we have now a connection with the lines across the Andes, and I may tell you that the other night we had a message from Lima to London and an answer to it in the short space of two minutes forty seconds. Probably that has never been equalled before, and at all events it shows that our connection is one which is capable of doing good work, and if good work will bring traffic, the traffic will come to us. I am hopeful that by that means this West Coast of America Company, which has been rather in the background for the last two or three years, will come forward again and pay us something for our investment, which we have continued to hold in the belief that it was certain to give us a return. Now, gentlemen, before closing these remarks I would like to mention what no doubt many of you who have read our reports from year to year must have noticed—that while the capital of this Company is over £3,500,000 and the work in our transfer office is ever on the increase, for we have 9,000 shareholders—the cost of working the Company is kept at a very low figure. Shares are being continually transferred, large holdings are split up into smaller holdings, and by this means the number of our shareholders is continually increasing. As you may imagine, this gives our small staff a very great deal of work to attend to, but nevertheless you will notice that our total working expenses amount to the small figure of 2s. 6d. per cent.—in other words, ⅛ per cent. only on the capital. I do not think there is much to beat that in the way of economy of management. At present the price of our shares will yield a return of £5. 5s. 10d. per cent. on the Ordinary and £3. 17s. 5d. per cent. on the Preference shares. The amount of the capital paid up is £3,602,690, while the present value of our securities is £3,920,536, showing a surplus balance of £317,846, or over £20,000 better than at this time last year. That leads me to refer to a gentleman who took the trouble, no doubt for some exchange operation, to endeavour to discredit us before the public. With that object he issued a circular, which I hold in my hand—it was in November last—in which he alleged that we were in a state of bankruptcy. We made a reply to his statements and our answer showed that we were in a very satisfactory and flourishing state indeed. The figures at that time were as follows: paid-up capital £3,602,690, while the value of our investments was £3,896,118, or a surplus of £293,428, whereas to-day, as I have said, we have a surplus balance of £317,846, taking our securities at the price we paid for them. There is an improvement in the market price of our securities of £20,418 over last year. That must be very satisfactory to you to hear, and I may state that the gentleman who wrote this circular was very ignorant of what he was writing about, and I think he will consider twice before making a statement again which he dared not repeat after we had met him. His circular caused a little feeling among some of the shareholders at the time, but our answer was so complete—and it is so much more complete to-day—that I am satisfied you will be pleased with it. I think that that finishes what I have to say respecting our own affairs, but I may add that telegraphs as a rule are now more or less influenced by the depression in trade throughout the country. They are also influenced to some extent by the laying down of new cables, and there are a great many rumours about other new cables being laid. Some of these rumours, I daresay, are true, or may become true; but whatever the result of the new cables may be to those who lay them, from a financial point of view, they will, at all events, secure a thoroughly efficient system of telegraphing for the general public. I only hope that the demand for the increased facilities thus afforded will to a large extent recoup any reduction of revenue which may be sustained by existing companies through the increased competition. I hope also that it may be more or less met by good management and good common sense on the part of the different Directions, and that they will not run into competition unduly, but will try and husband their resources, and promote to the best of their ability the interests with which they are entrusted. I now beg to move—

"*That the printed report and accounts for the year ended July 18, 1894, submitted to this meeting, be, and the same are hereby received and adopted, and that a dividend be now declared, payable on and after this day, of 3s. per share on the Preference shares, less income tax, and of 3s. 9d. per share on the Ordinary shares (income tax having already been deducted), making with previous payments a total dividend for the year of 6 per cent. on the Preference shares, less income tax, and of 4½ per cent. net on the Ordinary shares of the Company.*"

The MARQUIS of TWEEDDALE seconded the motion.

The CHAIRMAN: If anyone wishes to ask me any question now I shall be very glad to answer it. No one rising to address the meeting he put the motion and declared it carried unanimously. Continuing, he said: The next resolution that I have to propose is—

"*That Lord Sackville A. Cecil, who now retires, be, and he is hereby re-elected a Director of the Company.*"

Mr. JAMES PENDER seconded the motion, which was carried unanimously.

The CHAIRMAN then moved—

"*That the Marquis of Tweeddale, who now retires, be, and he is hereby re-elected a Director of the Company.*"

The Hon. ST. JOHN BRODRICK, M.P., seconded the resolution, which was carried unanimously.

On the motion of the Rev. C. F. BOOKER, Messrs. Deloitte, Dever, Griffiths and Co. and Mr. William Griffith, B.A., were elected auditors for the current year.

Mr. BOWES said he thought that the shareholders ought to be informed of the name of the gentleman or firm that made the attack on them to which the Chairman had referred. He would, however, be the last to press this point if the Directors had any reason for not mentioning the name.

The CHAIRMAN stated that the circular was anonymous, being signed "Scrutator." If the writer had had the courage to put his name to the circular the Directors would probably have dealt with him in a different way instead of "killing him" by their reply to his allegations.

A cordial vote of thanks was then proposed to the Chairman and Directors for their able administration of the Company's affairs, and carried unanimously.

Liverpool Overhead Railway Company.

The following is the report of the Directors to the twelfth ordinary half-yearly general meeting to be held at the Law Association Rooms, 14, Cook-street, Liverpool, on Tuesday, the 14th inst., at noon:—

The gross revenue receipts to June 30th amount to £20,044. 7s. 6d.

The number of passengers carried since the opening of the railway are as follows:—

	From March 6 to June 30, 1893.		Half-year ending Dec. 31, 1893.		Half-year ending June 30, '94.
First class	235,487	...	260,221	...	277,653
Second class	956,922	...	1,293,840	...	1,246.975
Workmen (special return tickets)	178,333	...	921,578	...	1,336,809
Total	1,370,742	...	2,475,639	...	2,861,437

During the past half-year 50,483 trains have been run, and 96 per cent. have been punctual.

The northern extension was opened on April 30th, and the traffic at the Seaforth Sands station has been very satisfactory. An arrangement has been made with the Liverpool Tramway and Omnibus Company to run omnibuses to this station, connecting it with the surrounding districts, and generally to act as feeders to the railway.

Two new stations have been opened at points where experience has shown it to be desirable to provide further accommodation, viz., at Nelson and Huskisson Docks, and a third will shortly be opened at Langton Dock.

Revenue Account.

	£	s.	d.
The gross receipts from traffic amount to	£19,658	13	11
Miscellaneous receipts	385	13	7
	£20,044	7	6
Less working expenses	14,947	5	6
	£5,097	2	0
From which deduct Interest on debentures and calls paid in advance...	2,639	7	7
	£2,457	14	5
Add balance brought forward from last year	2,598	7	1
Leaving available for dividend, the sum of	£5,056	1	6

Out of this balance your Directors recommend the declaration of dividends at the following rates (less income tax) payable on and after August 17th, viz.:—

5 per cent. per annum on Preference shares...	£2,170 13 8			
1 " " Ordinary shares ...	1,875 0 0			
		£4,045	13	8

leaving a balance of £1,010. 7s. 10d. to be carried forward to next half-year.

Manchester Edison-Swan Electric Light Company (Limited).

The twelfth ordinary general meeting of this Company was held on Monday last, at the Memorial Hall, Manchester, Mr. V. K. Armitage presiding. The Directors' report, which was taken as read, was as follows:—"The net profit, including last year's balance, amounts to £1,508. 17s. 5d., which it is proposed to appropriate as follows: To writing off balance of loss on Williamson Electrical Engineering Company, £940. 0s. 1d.; to special depreciation owing to change of showrooms, £256. 5s. 6d.; to special depreciation on stock of lamps on expiration of

Digitized by Google

patents, and to reduction in value of cables, £306. 11s. 5d.; balance to be carried forward, £6. 0s. 5d. The Directors view the result of the year's trading as satisfactory, considering the depressed state of trade during the last twelve months, and the fact that the Company's monopoly of the lamp trade has now ceased. They propose to write off the whole of the loss made on the Williamson Electrical Engineering Company (Limited), and the special depreciation shown above this year, and accordingly do not recommend the payment of a dividend."

The CHAIRMAN, in moving the adoption of this report, referred to the work that had been undertaken by the Company at Altrincham and Bowdon, and said he thought that from that installation the shareholders were justified in expecting a satisfactory financial result. He believed that in that and in other directions the future of the Company was hopeful.

Mr. F. B. ROSS seconded the motion, which was adopted.

Mr. F. B. Ross and Mr. W. P. James Fawcus were re-elected Directors.

A vote of thanks and £150 as remuneration for the past year was voted to the Directors, and the proceedings terminated.

Hong Kong Electric Company (Limited).

The report of the Board of Directors to the fifth ordinary yearly meeting of shareholders, held at the Company's offices, Hong Kong, on Monday, June 25th, expressed their satisfaction at being able to point to a steady progress in the Company's business, the working account showing a credit balance of $6,310. 94c., which, transferred to profit and loss account, left a balance to the credit side of $7,248. 47c.; while the amount overdrawn at the Company's bankers has, during the year, been reduced from $12,267. 17c. to $6,339. 97c. Although there had not been that rapid extension of the Company's operations which the Directors had hoped for, there was a steady increase in the amount of house lighting, and the benefit from the installations now being fitted would soon be showing itself in the earnings. It was not intended to fill the vacancy on the Board caused by the death of Mr. J. S. Lapraik.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1894, pages 274-300, *&c., &c.*]

CROPPER, CHARLTON AND COMPANY (LIMITED).—This Company was registered on July 28th with a capital of £2,000 in £1 shares, to carry on the business of (amongst others) machinists, mechanical, electrical and gas engineers, &c.

HARVEY CONTINENTAL STEEL COMPANY (LIMITED).—This Company was registered, on July 24th, to carry into effect certain agreements with the Harvey Steel Company, of New Jersey and New York, and to carry on the business of manufacturers of and dealers in armour and other plates, iron and brass founders, smelters, metal workers, boiler makers, machinists, metallurgists, engineers, manufacturing chemists, &c.

ROBERTS AND COMPANY (LIMITED).—This Company was registered on July 28th with a capital of £6,000 in £10 shares, to carry on the business of mechanical engineers, metal workers, boiler makers, machinists, electrical engineers, &c.

J. E. H. ANDREW AND CO. (LIMITED).—The annual return of this Company, made up to June 11th, has been filed. The nominal capital is £40,000 in £20 shares, of which 1,465 have been taken up, 300 shares have been considered as fully paid, and the full amount has been called on the remainder, resulting in the total payment of £24,000, which includes a sum of £700 received in respect of 35 forfeited shares.

KEIGHLEY ELECTRICAL ENGINEERING COMPANY (LIMITED).—The annual return of this Company, made up to March 17th, was recently filed. The concern has a nominal capital of £10,000 in £1 shares, of which 4,083 have been taken up, and 3,300 issued as fully paid. The full amount has been called and paid on 728 shares, while no calls have as yet been made upon the remaining 55 shares.

LONDON HEALTH ELECTRICAL INSTITUTE (LIMITED.)—The annual return of this Company, made up to April 29, was recently filed, when 6,007 shares, out of a capital of £10,000 in £1 shares, were taken up. Of these 6,000 were issued as fully paid to the vendors, and the full amount has been called and paid on the remaining seven shares.

NEW ZEALAND ELECTRICAL SYNDICATE (LIMITED).—The annual return of this Company, made up to December 31, 1893, was recently filed. No general meeting was held in 1893, owing to the non-receipt of the complete accounts from New Zealand. These have since been received. Out of a nominal capital of £30,000, in £10 shares, 2,955 have been taken up, and 2,000 have been issued as fully-paid to the Gulcher (New) Electric Light and Power Company (Limited). The full amount has been called on the remaining 955 shares, resulting in the payment of £8,040, and leaving £1.510 unpaid.

NORWICH ELECTRICITY COMPANY (LIMITED).—The annual return of this Company, made up to May 9th, has been filed. The concern has a nominal capital of £50,000, in £10 shares, and of these 2,382 have been subscribed for and allotted. The full amount has been called on each of these shares, resulting in the payment of £23,752. 10s., leaving £67. 10s. as yet in arrears.

OSWESTRY ELECTRIC LIGHTING COMPANY (LIMITED).—The annual returns of this Company, made up to July 15, 1893, and June 29, 1894, were both recently filed. Out of a nominal capital of £10,000, in £1 shares, 14 shares have been taken up, and upon these no calls have as yet been made.

J. H. PICKUP AND CO. (LIMITED).—The annual return of this Company, made up to June 14th, was recently filed, when the whole nominal capital of £15,000 in £5 shares were taken up. Of these 800 were issued as fully paid, and a call of £3 per share has been made on the remainder, resulting in the receipt of £6,600.

REUTER'S TELEGRAM COMPANY (LIMITED).—The annual return of this Company, made up to July 11th, has been filed. Out of a nominal capital of £100,000 in £8 shares, 11,839 have been taken up, the full amount called, and £94,712 paid.

ST. LUKE'S, CHELSEA, ELECTRIC LIGHTING COMPANY (LIMITED)—The secretary of the Chelsea Electricity Supply Company (Limited) notifies the Registrar that all the shares in the St. Luke's Company have been transferred to the members in the Chelsea Company, and that the name of the former should be struck off the register. It will be remembered that the Company was registered in 1890 with a capital of £1,000 in £10 shares, as the New Cadogan and Belgrave Electric Supply Company (Limited), as a reconstruction of the Cadogan Electric Light Company (Limited). The name was changed to the present title in 1892, the capital being raised to £30,000 in £10 shares, but only the seven signatories' shares were taken up.

J. G. STATTER AND CO. (LIMITED).—The statutory return of this Company, made up to May 4th, and recently filed, shows that 607 Ordinary and 340 Preference shares have been taken up out of a nominal capital of £20,000, in £10 shares. Of these 600 Ordinary and all the Preference shares were issued as fully paid. The full amount has been called on the remaining seven Ordinary shares, resulting in the payment of £10, and leaving £60 in arrears. The vendors, John G. Statter, Henry Foote, and Leonard Milne, hold all the shares, except four Ordinary and five Preference.

CITY NOTES.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended July 29th were £858 as against £824 in the corresponding period of 1893, being an increase of £34. The total receipts for the half-year amount to £3,458, as against £3,433 for the corresponding period of 1893, an increase of £25.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of July amounted to £2,800, as compared with £2,933 in the corresponding month of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of July amounted to £56,753, as against £62,317 in the corresponding period of 1893.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of July amounted to £42,873, and to £45,376 in the corresponding period of 1893.

KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend at the rate of 5 per cent. per annum on the Ordinary shares for the half-year ended June 30th last.

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee to allow £100,000 Five per Cent. Debenture Stock of the City of London Electric Lighting Company (Limited) to be quoted in the Official List in lieu of the scrip.

UNITED ALKALI COMPANY (LIMITED).—The Directors have declared an interim dividend of 7s. per share on the Preference shares for the half-year to June 30th. There is no distribution on the Ordinary.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended July 27th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £2,162.

WESTERN UNION TELEGRAPH COMPANY.—This Company has purchased the American Rapid Telegraph Company's undertaking, and has increased its capital stock by 5,000 shares. The Rapid Company defaulted in its interest and the property passed into the hands of a Receiver, who leased it to the Western Union at a rental of 60,000 dollars a year. The property was sold under foreclosure on March 11, 1891, to a committee of bondholders. The purchase of the Rapid Company's lines ensures economy to the Western Union Company in their operations, as compared with the terms of the lease.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 847.—Vol. XXXIII. FRIDAY, AUGUST 10, 1894. PRICE SIXPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

The destiny which led the British Association to Oxford this year, there to find as Chancellor of the University one of the few of our statesmen who have given serious attention to science, left no choice in the selection of a President. This destiny, a hard destiny in Lord Salisbury's opinion, has happily resulted in a notable address, which a less stern necessity might have failed to elicit. The serving-up by specialists of a palatable dish of tit-bits of their own particular science can be enjoyed at any meeting by the omnivorous *habitués* of the British Association. Sometimes, as at Nottingham last year, the public is allowed a glimpse of a burning controversy, or, as at Edinburgh, the artistic use of a scientific imagination will grant a vision of a prehistoric scene. But this year there is no labouring with minutiæ by a conscientious monographist, no graceful trivialities of a dilettante, but a broad survey of modern science and of its limitations. It is reserved for one who can stand at a distance, to obtain a true perspective view of the small, bright oasis of knowledge, and to discern the boundaries of the vast unexplored desert which still remains to be cultivated, and to be won. A shallow man taking this position might have tickled the fancies of his audience by trying to forecast the discoveries of the future; a dull one, to recount what has been done. Lord Salisbury chose to examine one or two instances of the obscurity that still hangs over some of the most important problems, and did not shirk the difficulties which he met. A bold man must be he who can stand up between Lord Kelvin and Prof. Huxley and call the ether a *modus vivendi*, and evolution "a comfortable word"; and bolder still is he who can to-day claim the attention of a British Association audience, even though sheltered behind the judgment of the greatest living master of natural science, for the argument of design.

The fact that we are under no obligations to find a theory, if the facts will not provide a sound one, cannot too often be insisted upon, and Lord Salisbury clearly drew a distinction between the necessity with which, as a politician, he was well acquainted, of taking some definite course, and the freedom of the man of science to wait for further developments. No Paper, or even preliminary note, on a new research is, as a rule, published without some attempt to supply a theory. A man may be a skilful experimentalist, and may have made some very useful contribution to the store of facts from which science is evolved; but he may be quite unfitted for discovering a theory. Many a careful worker and ingenious investigator has marred an otherwise valuable communication by thinking it to be his duty to append to the account of his experiments some hypothesis by which to account for his results. His discoveries, so far as they are new and accurately observed, are of some value, either now or in the future, but his theory may be perfectly useless. And here lies the great danger of which Lord Salisbury utters so clear a warning,—the acceptance of mere conjecture in the name and place of knowledge. How useful would it be if every writer on scientific research were compelled to distinguish his facts from his conjectures, making, say, the former his text and the latter his footnotes; and how delightful would it be sometimes to run through the one to see if they were new and interesting, and to leave the other until they could command attention.

The abstract of the researches of Elster and Geitel on the relation between atmospheric potential and solar radiation brings to a close a series of articles which have been translated by, or at the suggestion of, Dr. Oliver Lodge, in connection with the interesting experiment shown by him at the Royal Institution, namely, the dissipation of a negative charge on a piece of zinc by the action of ultra-violet radiation. Feeble as are the usual phenomena of atmospheric electrification, the aggregate result is probably much more important than is generally supposed. An occasional thunderstorm reminds us that the equilibrium has been disturbed; but we know, at present, but little of what is going on while that equilibrium is maintained. We could do without hurricanes, but not without wind. Thunderstorms are highly objectionable, but should we suffer if the annual and daily cycles of potential gradient were suppressed? The kindred subject of earth currents is still inexplicable, and even the comparatively tame and harmless variations of terrestrial magnetism have, in Prof. Rücker's opinion, received but little attention, except for the utilitarian purposes of geography and navigation. It is possible that these three, atmospheric electrification, earth currents, and terrestrial magnetism, are bound up together, and, so far from being a simple periodic flux like the tide, are connected by far more complicated forces than that of gravitation with both visible and invisible radiations of the sun, or if the sun is too small to account for them, to some grand external influence of which absolutely nothing is known.

The news that the business of the London Electric Supply Corporation has passed into the hands of a receiver appointed

Digitized by Google

by Lord WANTAGE will come as a blow to all electrical engineers who have followed the vicissitudes of this bold undertaking with interest and sympathy. It is but one more instance of the futility in commercial and engineering affairs of splendid courage unless supported by something more prosaic. Fortune, it must, however, be admitted, has been peculiarly unkind to the sanguine backers of Mr. FERRANTI; burn-outs and break-downs, most of them at particularly inopportune moments, have marked the history and hopelessly retarded the development of this concern; and, except to the *ex post facto* wisdom of the well-known "I told you so" type, the majority of these mishaps were distinctly beyond control.

THE *immediate* commercial success of the enterprise financially fathered by Lord CRAWFORD, Lord WANTAGE, and Sir COUTTS LINDSAY was entirely dependent upon the success of a fine piece of strategy, which at the time it was conceived appeared to have every chance in its favour. At a date when most of the companies now at work in London were in a very embryonic stage of development, without capital, business, experience, or powers, the London Electric Supply Corporation possessed three out of these four requisites, and, had it been able to maintain its lead in this respect, and arrive first in the field, the £850,000 which has been sunk in this plucky endeavour to capture the electric-lighting business of the metropolis would now have been reaping an adequate reward. As it is, there is nothing to be done but to hope that the undertaking will *ultimately* realise the anticipations of its promoters, and to offer our sympathies to the unfortunate shareholders, who, at any rate, have not experienced the added misfortune of being kept in the dark until the ship was right on the rocks.

SOME two years ago Lord WANTAGE, whose ordinary and preferential stake in the concern amounts to the respectable sum of something like a quarter of a million sterling, lent the Company £50,000, secured on the whole of its undertaking, and it was the inability of the Company to repay this loan that obliged Lord WANTAGE to take the step he has, those with the next largest holdings being quite satisfied that there was nothing else to be done under the circumstances. The concern will go on as before, with the difference that it will be possible for Lord WANTAGE alone to effect economies in the working, which it would perhaps be difficult for a Board to do. He has shown his anxiety to study all interests by appointing Mr. BAIN as his receiver and manager, and, as this gentleman is still Secretary to the Company, there are no conflicting interests, as might have been the case had the matter been handed over to a member of a firm of actuaries. It may be of interest to state that there are some 860 Ordinary and 210 Preference shareholders; Lord WANTAGE, Sir COUTTS LINDSAY, Mr. HENRY OPPENHEIM, Lord CRAWFORD, and Mr. CHARLES MORRISON holding between them over £300,000 of Ordinary shares.

FOR the modest sum of one halfpenny the constituent items of the great British public may procure for themselves a Return to an Order of the Honourable The House of Commons, showing the number of telegraphists in the service of the Post Office in London and the provinces, together with their wages and conditions of employment in 1891 as compared with 1872. In 1872 the Postal telegraphists numbered in all some 5,200; to-day they number nearly 9,600 of both sexes; an argument, if one be needed, that service conditions are not altogether so intolerable as some would have the public believe. But what are these conditions? First-class telegraphists, it would seem, now receive in London an average salary of £135, with a maximum of £160, and the general body of employés an average salary of £76, with a maximum of £110; the average of the former being some 15 per cent. and that of the latter some 24 per cent. higher than was the case two-and-twenty years ago. When with this, by no means inadequate, remuneration, are coupled such considerations as permanent employment, pension, regular holidays, payment during sickness (full pay for first six months, half pay for next six), free medical attendance, overtime pay for Sunday labour, tolerable hours, &c., we are at a loss to discover just where these grievances, about which we hear so much, come in. The average members of the electrical profession, and indeed of the general public, may well envy the average lot of the average postal telegraphist.

IN the early days of electric lighting it was a common practice to use "banks" of glow lamps for testing dynamos, and for other experimental purposes. These gave place to resistances of iron or other wire as soon as ammeters could be bought, but the reduction in the price of lamps makes lamp rheostats again practicable, and this very simple and convenient form of resistance is to be found in nearly every laboratory. Many ingenious switches have been designed for connecting resistances in series or in parallel, and most of these aim at putting the whole in parallel, the whole in series, together with many intermediate combinations. A convenient arrangement is described in a recent number of the *Electrical World* of New York, in which ten lamps are used, each of sixty ohms resistance. One, two, or three can be put in series, and of the remaining seven, any number can be put in parallel. This gives a range of from 180 to 7·5 ohms, and gives 24 combinations.

THE American daily papers are sometimes disposed to take the romances of science too seriously, and to think that the speculations of enthusiasts are redeemable at par on demand. They are therefore unable to understand that the predictions of future illumination by Teslaic processes are not affected by any such sordid considerations as mere time limitations, but must be taken as promissory notes to a future generation. One of these newspapers recently presented its readers with a number of illustrations, designed to show what things will be like when we "have light, not lights." Light, we are told, "will well impalpably out of walls," or will shine on us like "a century plant in unending bloom, of which the petals are sheafs of light." An illustration shows one of these flora planted on a footpath in front of someone's doorsteps, and it bears a striking resemblance to a cocoanut palm over which several buckets of whitewash have been thrown. Another

Digitized by Google

illustration shows a ballroom, the walls of which are welling —not impalpably—with spiky streaks of something intended to be light, but which has the appearance of an anti-burglar frise. We notice that this form of illumination casts deep shadows!—but perhaps that is the fault of the artist.

Cable Interruption and Repair:—

	Date of Interruption.	Date of Repair.
Para-Maranham	July 23, 1894.	August 3, 1894.

British Association at Oxford.—The number of tickets taken up to 6 o'clock on Tuesday evening last was 1,472, compared with 1,114 at the corresponding period last year. The tickets taken by the time the meeting commenced on Wednesday, amounted to 2,134.

"Electric Power."—Mr. Horatio A. Foster, who is now associated with Prof. George Forbes as his representative in America, has become the editor of *Electric Power*. Mr. Foster was one of the staff on electrical work of the last United States Census, and has long made a close study of electrical technics and statistics.

Gas and Electricity in London.—At the last meeting of the Gas Light and Coke Company the Governor, in defending his Company against the South Metropolitan Company, pointed out that his Company had had the electric light to contend with, "which had stopped their increase, though it had not caused them to have a decrease."

Automatic Railway Ticket Machines.—Railways worked on the single fare or zone system can very easily dispense with booking clerks, for whom the automatic penny-in-the-slot machine may be substituted. The North London Railway Company has recently adopted the automatic method for distributing tickets for the workmen's trains.

Electric Traction in Madrid.—The shareholders of the Madrid Tramways Company have unanimously decided to adopt electric traction on their system. A Brussels concern will equip the tramway according to the provisions of a scheme drawn up by the Allgemeine Elektricitäts Gesellschaft, and will work the line at so much per car-kilometre.

Meter Rentals.—At the last meeting of the Gas Light and Coke Company Colonel Makins announced that his Company was prepared to abolish meter rentals if only the South Metropolitan and Commercial Companies would do likewise. Meter rents bring in an annual income of £58,000 to the Gas Light and Coke Company, notwithstanding that no rents are charged within the City area.

Geneva.—The Town Council of Geneva has decided to place three two-phased alternators at the new hydraulic power station, which is situated five miles below Geneva. These machines are being manufactured by the Compagnie de l'Industrie Électrique, of Geneva, and they will be direct-coupled to the turbines. The output of each machine will be 1,200 H.P., at a speed of 80 revolutions per minute.

A New Use for Magnetism.—"Ballistic" circles have been much exercised of late by the new Russian "secret" armour piercing projectile. The opinion of experts is that the secret consists in the projectiles having false points or caps fixed on their apices. As they have been called magnetic shot it is suggested that magnetism may have been employed to hold the cap to the smooth apex of the shot.

The Pacific Cable Question.—According to a Reuter telegram, dated Ottawa, August 6th, the Canadian Government, under the authority given it by the recent Inter-Colonial Conference, is inviting tenders from cable manufacturers for the laying and maintenance in an efficient condition of a cable across the Pacific from Canada to the Australasian colonies. Offers will be received to November 1st next.

Fire at an Electric Works.—The gutta-percha coating of a quantity of telegraphic wires stored in the cellars of the electrical works at 226, Rue Saint-Denis, Paris, caught fire last Saturday afternoon, and the flames were spreading forth when the danger was discovered by a workman. He succeeded in extinguishing the fire, but had a narrow escape of being suffocated by the fumes of the burning gutta-percha.

Obituary.—Miss Ellen Webb, the last surviving sister of Mr. F. H. Webb, Secretary of the Institution of Electrical Engineers, and Mr. F. C. Webb, expired at her Hove residence last Saturday. Miss Webb was well known and much respected in temperance circles, and was an enthusiastic supporter of the Salvation Army and its leader. She was known in the Hove and Brighton districts as a generous donor to numerous local and other charities. Her death was quite unexpected.

Wiring Charts.—With reference to the chart published as a supplement to our issue of July 20th, Mr. W. M. Mordey reminds us of a very convenient scale which he showed us some months ago, and which resembles Mr. Sanders' scale in several particulars. We have been reminded also that Mr. A. H. Howard has constructed an elaborate chart of wire gauges, &c. These are, of course, all independent productions.

The Telephone in Birmingham.—We have always understood that outside London the telephone service was all that could be desired; evidently we have been long labouring under an erroneous impression. The *Birmingham Post* has lately been filled with the wailings of the local telephone exchange subscribers. The following is a sample letter:—

Sir,—Your correspondent "Disappointed" puts his complaint in a most mild form. I consider the telephone management in Birmingham is disgraceful. You are either told, as "Disappointed" states, that the firm you require is "engaged," or the line is engaged, or the instrument is out of order; and frequently when you do get through you are talking with two or three voices mingling with your own. You ask for an explanation, and you are told it is "induction." DISGUSTED.

The Wear of Tramway Rails.—In a Paper read before the Tramway Institute, by Mr. T. Arnall, of Birmingham, the author states that trouble has been experienced with girder rails on the tram-lines of that city, owing to the uneven wear of the head and the projecting flange of the groove. Owing to this the flange of the groove projected above the rest of the rail, and became a nuisance to the ordinary street traffic. This trouble does not arise on horse lines where the traffic is not so great, as the wear of the groove flange is then not much less than the rail head; but with the heavy traffic of the steam lines it had become necessary, for the reasons stated, to remove rails long before they were actually worn out. To avoid this trouble in future, Mr. Arnall suggests the use of a girder rail with a central groove.

Copper.—The explanation of the low price of copper, which is only a shade over £38 per ton, is, says *The Statist*: 1. The necessities of producers in the United States to realise cash, and selling largely to Europe. 2. The small consumption in the United States consequent on the depression in trade. 3. The indisposition of consumers to buy at a time when the market has been declining. 4. The working off during the last four or five years of the great accumulations that occurred when copper was carried up to an abnormally high level, and invisible supplies of old copper were accumulated to the extent of, perhaps, not far short of 50,000 tons beyond the large accumulations brought about by mines being put into work when prices were at a high level. In the opinion of our financial contemporary the time is at hand when a turn in the tide is likely to be witnessed.

The Steam Jacket.—A paper was read at the recent meeting of the American Society of Mechanical Engineers by Prof. R. H. Thurston on the theory of the steam jacket. The paper described the method of action of steam jackets and the sources and limits of the efficiency. Prof. Thurston at one point states that "the final result of experience up to date may be summed up in the statement that when a jacket is properly designed, constructed, and attached, and when it is properly manipulated, it may always be expected to give good economic results in simple engines, and large returns on the investment, with all classes except, possibly, the high-speed engines." The author believed that it was still a question whether the unsatisfactory reports from its use on fast-running engines may not be attributable to defects in jacketing rather than to limitation of the system to slow-speed engines.

A Forecast.—Mr. R. J. Jack, the Government Geologist of Queensland, in reporting upon the Ipswich coalfield of that

Digitized by Google

country, has been giving free play to his imagination. "I can see the time," says Mr. Jack, "when the fuel will no longer be roughly handled, and at a great unnecessary cost in its transport to the city and to the distant ports, whence it has to be distributed to where it is wanted for the various purposes of human industry. I can see the coal shot into furnaces at the mouth of the pit, smelting the iron ores of the district, required for a host of native manufactures, and transmitting power and light, and the vehicles of locomotion, by means of electric cables, to other industrial centres. I can see, further, that the extension of the use of electric cables, not only from Ipswich, but from other at present impracticable coalfields, will make copper mines no more a drug in the market, but eagerly sought after."

Telephonic Marvels.—A correspondent of the *Dundee Advertiser*, writing from Broughty Ferry last Wednesday week says:—"I had an interesting experience this afternoon. A friend rang me up by telephone at my house in Broughty Ferry from the Highland Show yard in Aberdeen, and whilst he was speaking to me he said—'Wait a minute; I can't hear what you are saying for a pipe band which is presently passing the telephone booth.' I instantly replied—'I was just hoping you would stop for a minute, as I wanted to hear the band.' The wire was fortunately in very good order to-day, and not only did I hear the pipe music, but I distinctly heard the tramp of the men as they walked past. The tune they were playing was The Barren Rocks of Aden, and it was a most interesting experience to hear pipe music and 'the tramp of armed men' over 150 miles of wire. I have repeatedly before heard by telephone a common eight-day clock striking and piano music at a distance of over 100 miles, and have heard a watch ticking at a distance of about a mile, but I have never until to-day had the pleasure of hearing over the telephone music played in the open air at a distance of considerably over 100 miles."

The Cottrell Telephone Transmitter.—In our issue of January 8, 1892, we described at length an ingenious telephone transmitter devised by Mr. Charles Cuttriss, in which the motions of the microphone diaphragm alternately elongated and compressed a delicate spiral of springy carbon, the complete rupture of the circuit at any moment being in this way rendered impossible. A telephone transmitter on the same principle has recently been brought out by Mr. Herbert Cottrell, of Newark, New Jersey. A thin strip of carbon, from which project knobs or points that are but lightly, if at all, in contact with each other when the strip is straight, is bent into an arch between the telephone diaphragm and the back of the instrument. The backward and forward motion of the diaphragm successively stretches the strip straight and bends it into a bow, the knobs successively separating and coming into contact. No movement of the diaphragm can possibly rupture the circuit, since that is always complete through the base of the carbon strip, along which the variable contact shunting projections are arranged. Obviously the resistance will be greatest when the circuit is completed only through the base. The resistance of the projections is preferably made considerably smaller than the resistance of the base along which they are set.

Power Transmission in California.—In a recent issue the *Electrical Engineer* of New York gives an account of a proposed Californian power-transmission scheme. The first project is one of transmitting power electrically from Clear Lake to San Francisco, a distance of 75 miles. It is proposed to run three lines of steel pipe of 5ft. average diameter a distance of 40,800ft. to the generating house, where the water delivered under 151ft. head at the Pelton wheels will furnish a total of 28,950 H.P. At 72 per cent. loss, this would net 20,845 H.P. in San Francisco. It is proposed to employ 1,000 H.P. generating units and 25,000 volts pressure on the line; and two overhead lines, each carrying 10 circuits. The total cost is estimated at £800,000 in round figures. Fuel is costly in San Francisco, and power costs £2 per horse-power per month. The Clear Lake Company intend to sell it at £1 per month. It is stated that San Francisco, with its 300,000 population, is now ninth in the Union in manufactures despite the high cost of fuel. Its power plants aggregate 60,000 H.P. The conditions are favourable, therefore, for a large utilisation of cheap water-power from a distance, and, as the climatic conditions are also good, there is no reason, on the surface, why the Clear Lake transmission should not prove quite feasible.

Lightning.—During the past few days lighting has been doing more than its normal amount of damage. Last Sunday morning it struck the 90ft. high tower of the village church of Norton-sub-Hamdon, in Somerset. The sacred edifice is not protected by any lightning conductor. On the roof is a flag-staff, with a pulley and metallic chain attached. The lightning struck this, evidently mistaking it for a regular conductor. It must then have gone through the roof to the brass-work of the clock, and thence to the floor of the chamber. This floor had been cased with deal, and here the fire originated, which got complete mastery of the tower.—Early in the week, during a wedding at Thanington Church, which is about a mile from Canterbury, a cabdriver named Joseph Bennett was killed by lightning. During the storm Bennett took refuge under an elm tree on the other side of the road, holding the horse's head. Both he and the horse were struck by lightning and instantly killed.—During a thunder-storm at Potsdam on Tuesday, the New Palace was struck by lightning shortly after four o'clock. The current followed the telegraph wires and set the fire alarm apparatus in motion, causing the firemen at the Palace and the town engines to turn out. No damage was done to the building.—From Ssenkowo (Russia) comes the story of an extraordinary case of a man being struck by lightning during a storm which was taking place at a distance of 107 versts, or 71 miles, from the spot where he was working. The workman was engaged in putting up a wire on a telegraph post, when he suddenly feel down dead. There were 13 burns discovered on his body. At the moment of the man's death the sky over the town was quite clear and bright, and there was no trace of a thunderstorm, but at the same time in Wladimir, 107 versts from Ssenkowo, a very heavy storm was raging.

The Blackpool Tramway.—An extraordinary statement was made at the meeting of the Blackpool Town Council on Tuesday by Mr. Councillor Pearson anent the state in which the electric tramways had been found. They found, he said, that the main difficulty was in the station itself. The difficulties they had encountered were not electrical but mechanical—difficulties that ought never to have arisen, inasmuch as they were due to want of attention. In company with Mr. Holroyd Smith, the Committee examined the shed, and found a state of things that was positively disgraceful, and for which somebody was greatly to blame. The tubes of the boilers were so choked with dirt and filth that it took two men six days to clear them out. The dynamos were in a similar condition; the foundations and frame-work were rotten; in fact, the whole plant was giving way for want of attention and proper repair. The armatures were in a bad condition, and the fire-boxes of the boilers were ten inches deep in thick mud. The cylinders themselves were in a similar condition, and the steam-pipes were so thickly coated with oil-paste that they could not possibly have been cleaned out for twelve months! The dampers were all stuck fast and rusted up, and the main shafting was badly worn, and not to be depended upon. Those things had now been remedied. Four practically new cars had been placed on the track, with motors fitted with Mr. Holroyd Smith's worm-gearing, and they had ordered two new bogey-cars. Mr. Pearson then went on to say that it was to their certain knowledge that they had had enemies on their track almost the whole of the time they had been trying to remedy these defects; someone with a knowledge of electrical matters had tried to interfere, not only with the tram lines but with the electric lighting. Only the previous day he had brought to him a chain which had been placed round the copper rod (in a scientific way), which conducted the current entirely to earth. That was not the first time they had discovered such interferences. They had a multitude of evidence in the shape of spades, nails, small pieces of iron and copper, which had been laid in a proper manner by people who knew what they were doing. It was their intention to ask the Watch Committee, along with the Chief Constable, to try and detect those malicious persons.

HEINRICH HERTZ.

The portrait presented to the reader to-day is that of the man with whom science at the commencement of this year buried its best and richest hopes. Hertz was in our midst but 37 years. The 20 years of earnest labour claimed by Faraday as necessary to the full development of the philosopher's mind were barely allotted to him, and yet we know his works rank with the highest achievements attainable by a human mind. And now that we have begun to know and fully appreciate him, we have already lost him, and with him all that so rich a mind holds latent, and all that it would have disclosed, both of itself and by its influence upon others. His works lie open before us from the first research to the great electrical investigations, and from these, again, to the "Principles of Mechanics." He will add no more to these.

If, to estimate our loss fully, we cast a glance into the Past, and search for men who with similar masterly insight have penetrated the complexity of the Known, have selected elevated standpoints from whence to perceive the great landmarks in the dim and distant Unknown, who as surely reached them, and who have succeeded in doing all this at an equally early period of life, we meet with the most consecrated names written in the history of science. It was the same philosophical spirit that, once in Newton, revealed a hidden world by means of a simple prism of glass, now in the person of our genial fellow-worker, performed the same by means of feeble sparks. The same power of abstraction, the same keen insight produced formerly the method of fluxions, now that system of ideas to which the "Mechanics" owes its mathematical form. The same mental power viewed Nature as a whole and summed up its operations aforetime in three laws, now in one single law of simple meaning.

The external life of Hertz was as simple and straightforward as himself. He was born at Hamburg on February 22, 1857, being the eldest son of Dr. G. F. Hertz, who was at that time a lawyer, and is now a Senator, and at the head of the legal administration of the Hanse Town. His mother came from Frankfort-on-Main. From his father he seemed to have his noble pride and his practical turn of mind; from his mother his amiable disposition. The great talent which he early displayed, and the deep sense of duty which distinguished him even as a boy, made him the especial favourite of his parents, who bestowed every care upon his education. He received his first school training at a private school in his native city, which he attended until the fifteenth year of his age. He did not, as is usual in Germany, pursue the course of classical study at the gymnasium; but he read the ancient classics with zeal and pleasure at home, and so thoroughly mastered them within two years that he was admitted to the final course at the Hamburg Gymnasium known as the "Johanneum." A year later, at the age of eighteen, he left this school with a certificate testifying to his fitness for university studies. In addition to his school tasks he practised mechanical work at home. His favourite occupation was working at the carpenter's bench. He constructed wheels for himself to convert his bench into a lathe, and he made many kinds of physical apparatus as he wished to have them, in order to observe this or that phenomenon. He was likewise fond of drawing and painting. Scientific books he eagerly seized upon, and he used every spare moment to study them until he could tell his parents "I have now mastered that book," and this invariably proved to be true. He successfully ventured upon the study of the most difficult branches of mathematics during his school days.

When at length the time came for Hertz to choose a profession, he determined to become an engineer. The choice disappointed all his teachers. He, too, greatly desired to pursue the study of pure science; but his natural modesty led him to doubt the possibility of his ever making any satisfactory progress towards those ideals of science which his striving mind had in view. He preferred to rely on his taste for mechanical work. Consequently, he worked for a year in the municipal engineering office at Frankfort-on-Main, where the great bridge over the Main was then in process of construction. Many designs, executed with admirable care, testify to the zeal and earnestness with which he devoted himself at this time to his chosen calling. He then went to the Polytechnic in Dresden, where he remained, however, only half a year, being then called upon to fulfil his term of military service. In the autumn of 1877 he went to Munich, intending to continue his studies at the Polytechnicum of that city. But, as he read over the syllabus of the classes and realised, more clearly than before, the nature of the work which was to occupy him now and probably throughout his life, he began to feel dissatisfied. He had attended lectures on the steam-engine in Dresden; they aroused his intense interest, inasmuch as they revealed to him the secrets of the mechanical theory of heat; the technical details, on the other hand, were unable to offer any interest to him. These details proved burdensome to a mind striving to reach the summit of perfection, and the load now began to be intolerable. He therefore resolved to go over to the university. The resolution was for him no easy one. It caused him to rely entirely upon those faculties he so longed to set at work, but on which as yet, in their unproved state, he had little reliance. He was strengthened, however, in his resolve by the assent of his parents. After studying for a year at the University of Munich he went to Berlin, and became the pupil of Von Helmholtz and Kirchhoff. It was Von Helmholtz in particular who exercised the greatest influence upon the whole course of his thoughts and views. Hertz therefore retained throughout his life an especial attachment for him, and a characteristic childlike gratitude towards him. After only one year's work in the laboratory of Von Helmholtz he completed his first original investigation, in which he seeks to answer the question whether electricity in motion possesses inertia. Tendered with words of rare praise from the lips of Von Helmholtz and Kirchhoff, the work gained the gold medal offered by the Philosophical Faculty for the solution of the problem. It happened also about that time that Von Helmholtz drew the attention of the 22-year-old student to the prize problem of the Royal Academy of Sciences of Berlin, referring to the proof of Maxwell's theory, and offered him the assistance of the Institute in case he decided to carry out the research. Hertz himself tells us in his work "On Electric Waves" that he thought over the subject, and finally gave up the attempt, realising that the methods then known were inadequate. But he retained in his mind for eight years the deep impression made upon him by this request of Von Helmholtz, until the discovery of new methods enabled him to achieve success in his famous electrical researches.

Soon after this first work Hertz obtained the Doctorate, with a theoretical dissertation, in which he solved the problem of Foucault currents with a generality including all previous solutions as particular cases. He was appointed assistant to Von Helmholtz, a post which he held three years. During this time he produced an excellent series of researches, both experimental and theoretical in character. Their number, twelve, testifies to the enormous capacity for work their author possessed, while we see in their contents with astonishment how wonderfully he mastered, even at that time, theory as well as experiment. It is indeed difficult to find any difference between these early researches and his later famous investigations, unless it be in the smaller influence which the early works have exercised on the progress of science. Nevertheless they by no means treat entirely of out-of-the-way subjects. In one of them, for instance, along with the solution of most difficult problems in the theory of elasticity, he has given for the first time clear insight into the nature of a universally known property of bodies, which had nevertheless been only dimly and vaguely comprehended, namely, that of hardness. Or, again, from another communication, "On the Pressure of Mercury Vapour," we learn by Hertz's characteristic combination of theory and experiment that this constantly-occurring pressure at ordinary temperatures is nearly one hundred times smaller than usually assumed. A peculiar charm of these, as well as of all his writings, is due to the clearness and profundity of thought, but none the less to the simple and yet striking manner of representation. His works reflect his own character, which was as simple and straightforward, as true and steadfast, as the operations of Nature herself.

In the year 1883 Hertz left Berlin, and, following the advice of Von Helmholtz, settled down as Privat-Docent at the Univer-

Digitized by Google

sity of Kiel, where he received a teaching appointment from the Prussian Minister. During his stay of two years he was occupied exclusively with theoretical investigations, there being no laboratory at his disposal. Although always conscientious in the employment of his time, he used to enjoy occasional pleasure parties by steamer or yacht in the harbour of Kiel. Perhaps it was these trips that led his thoughts to the study of atmospheric phenomena, which formed the subject of one of his investigations at that time. But he ever liked to come back to the subject of his first work, electro-magnetics, upon which two very important communications were published by him about this time. Ere long he was to harvest the well-deserved fruits of his persevering activity on this field of research.

Hertz was now twenty-eight years of age. Held in high esteem by all his fellow workers, by a few already recognised as the rising sun of a new epoch, he received almost simultaneously three calls to professorships, in Greifswald, in Kiel itself, and in Karlsruhe. He accepted Karlsruhe, being well pleased with the laboratory. There, in the capital of Baden, he became acquainted with Elizabeth, daughter of his colleague Dr. Doll; he won her heart and soon afterwards made her his wife.

Then began the happiest period of his life. He observed the small sparks at the ends of a Riess spiral used by him in a lecture, and the very fact which so many had previously passed over became for him the starting point of those researches, the impression of which is still fresh in our memory. New properties of the ether have been revealed. Electric phenomena have ceased to stand isolated as if they were exceptional conditions artificially produced; they exist everywhere—light is an electrical phenomenon. A supposed action-at-a-distance is proved to require time for its propagation. The rambling old building of electro-magnetic theory, already shaken by Faraday and Maxwell, collapsed and totally disappeared; in its place the new building stands firm and shapely.

The recognition of such work was not wanting; it is now consoling to know that it came so quickly. Hertz was soon invited to become the successor either of Kirchhoff in Berlin or of Clausius in Bonn. He preferred the latter, and went to the Rhenish town in the spring of 1889. England, also, was not backward in doing honour to his success. The Rumford Medal was awarded to him; the Literary and Philosophical Society of Manchester and the Cambridge Philosophical Society each elected him as an honorary member, and the London Mathematical Society conferred the same distinction upon him. The latter especially pleased Hertz, as being a particular recognition of the mathematical merits of his researches. He became a member of almost all the chief Continental Academies; various great prizes were awarded to him. But let us not linger over the enumeration of his honours, it would only divert us from the image of this ever modest man, still present in our memory and still retaining its old magic charm over the hearts of those who knew him. To describe fully this noble character would be beyond my feeble powers. Let me only attempt to recall some of its many lovable traits. Great modesty was the main feature; it permeated his whole being, and led him to keep his personality in the background in the presence of old and young alike. This modesty was accompanied by an anxious desire to spare the feelings of others. He displayed unvarying kindness to all those who came within the range of his influence, and most especially to those in the laboratory who were associated with him in his capacity as Director. His was an intensely sympathetic nature. To cheer and encourage others was for him a delight. It was to his charming manner and amiable disposition, no less than to the exceeding greatness of his merit, that he owed the singular good fortune never to encounter petty jealousies or animosities. He was ever ready to fully acknowledge the merits of others, and give honour where honour was due, and nothing roused him so much as to see such merits undervalued or slighted. His tender, unassuming nature, his great modesty, could not, however, conceal the mighty power of his intellect. The striking and forcible thoughts he could produce at any moment gave him the superiority in discussion, and they lost none of their impressive power by the unassuming form in which they were uttered. To be, however, considered as an authority in his science, even by the youngest beginner, was a thought which never entered his mind. In daily life he quickly perceived the comic side of things, and used to season his narratives with such rich and sparkling humour, that it was a positive treat to listen to him. He liked to attack in a playful way such thoughts as were wanting in clearness. But it was only in his later years, that this humorous disposition developed, in his earlier life his reticence and reserve, the outcome of a deep and earnest nature, preponderated.

Hertz made but few demands upon the equipment of the laboratories of which he was Director. Indeed, almost all his results were obtained with the simplest contrivances and with external means known long before. He also liked to set up his own apparatus, using such materials as he could find near at hand, and with the simple tools which he had possessed from his youth. He thus accomplished his purpose with an astonishingly small expenditure of time and material. By all sorts of ingenious devices he knew how to make use of the properties of the commonest substances. Yet he did not set any value upon his devices, sometimes even forgetting them entirely, to rediscover them later on. They were secondary matters; it was the great ends that he had in his mind. He liked to work alone; the presence of an assistant seemed to distract his thoughts. In his later years he read but few scientific works; indeed, in most cases a glance between the pages was apparently sufficient to enable him to gather the essentials of the contents.

For three years and a-half Hertz thus lived happily in Bonn, perfectly content in his sphere of activity. Then, in the autumn of 1892, a malady began to show itself; apparently insignificant at first, but slowly and continuously undermining his health, which until then had been excellent. The seat of the illness seemed to lie in the cavities of the nose. In the following winter an operation behind the right ear was necessary to remove the danger threatening his life. It was successfully performed, and every hope of his recovery was entertained. He resumed his lectures in the spring of 1893, continuing them until early in December, though at the end with evident effort, as the symptoms of the malady returned in an increased degree. From this time the course of the disease was rapid, and ended in blood-poisoning. On the afternoon of New Year's day this year death released him from unspeakable suffering, borne with heroic fortitude. His remains are interred at Hamburg.

In the last three years of his life Hertz completed a work on "The Principles of Mechanics." He left it to science as a legacy. It was given to the world only a few days ago. In this magnificent work he shows us the universe from a new point of view, to the deep satisfaction of the mind convinced of the simplicity of Nature, existing, but hidden from the narrow standpoint of our five senses. For a long time past natural philophers have agreed that all natural phenomena are to be traced to the simple laws of mechanics; but which these simple laws may be, this is not agreed upon. It is not certain which definite combination of mechanical principles is necessary and sufficient to embrace all known processes of Nature, and at the same time to exclude every process the occurrence of which is already excluded by experience. The combination usually used is formed by Newton's three laws, together with D'Alembert's principle. But are the forces of which Newton's laws speak of a simple nature? And, in order to have the laws assert neither too little nor too much, which properties should be ascribed to these forces? and of what nature are we to assume the connections between the parts of natural systems, entering into D'Alembert's principle? In the two latter questions are expressed the uncertainties of this first combination of mechanical laws, and, moreover, the idea of "force" introduced here into the fundamental principles loads them with inner contradictions. The second known possible combination of mechanical laws is formed by the principle of the conservation of energy, and by one of the integral principles—for instance, Hamilton's principle. Here it seems doubtful from the beginning whether this combination is really sufficient to account for all natural processes. Again arises the question as to the real range of the mechanical principles. Which phenomena do they embrace, which not? And what is the real inner meaning of laws as complicated in

Digitized by Google

form as those integral principles? Moreover, is the idea of "energy" with its twofold nature at all fit to be introduced into the fundamental principles? All these uncertainties and doubts must have been felt by all whose wish it was to grasp the deeper meaning of mechanics, of the existence of which the mind is convinced; and the inner contradictions are painful even to the beginner in this science.

Hertz deals with all these questions in the introduction to his work; he brings to light the existent inner contradictions with words of impressive simplicity. In the contents of the work itself he gives a solution of the questions, completely removing the contradictions. He gives a thoroughly definite combination of mechanical laws, which is neither too narrow nor too wide. And he gives it in the form of one single Fundamental Law of the greatest simplicity and lucidity. This Fundamental Law speaks of spaces, times, and masses only. The ideas of force and energy with their difficulties are removed from the foundation. He shows us all the known general laws and principles of dynamics as fragments of this single Fundamental Law or as applications of it to particular cases. The range and the inner meaning of each law and principle is revealed thereby with wonderful clearness and precision, a clearness and precision attainable only by such keen logical reasoning as was peculiar to Hertz. Ordinary mechanics now appears as a special case of Hertz's new system of mechanics, inasmuch as ordinary mechanics deals with the motions of masses directly perceptible by the senses. If we consider these masses by themselves we are always confronted by complex and unintelligible laws. But if we add to these masses the intangible masses of the existence of which physical science is now fully convinced, and if we ascribe to these masses properties and motions possible in every way, and for all we know probable, then we obtain a connected Universal system based on the one Fundamental Law. The law states that "Every independent system of Nature moves with uniform velocity along one of its straightest paths." The possibility of expressing this universal law by such simple words is due to the use of a new system of kinematical ideas, such as "velocity of a system," "straightest path of a system," adapted to Nature, the discovery of which excites our highest admiration. To the construction of this system of ideas the "First book" of "Mechanics" is devoted, whilst the "Second book" gives the development of the known contents of mechanics, in a wide sense, from the Fundamental Law.

The system of Hertz's mechanics is, strictly speaking, only a hypothesis, which is not contradicted by any known experience, but which asserts more than can be proved as yet by positive experience. Standing there, however, in unique and marvellous beauty and perfection, like Nature, the system bears already in itself the character of the utmost probability. And the very fact that in its statements it goes beyond the limits of present experience makes it appear all the more adapted to become a guiding star for future discoveries of new general truths. On Hertz's Mechanics hang now all hopes of ever getting essentially nearer the goal towards which for ages the human mind has striven: tracing back Natural Phenomena to simple, general laws. A firm basis to further progress is now given. The greater the difficulties still to be overcome may appear at present, the further a creative mind has gone beyond us here: the deeper will be the influence of that mind upon all further development of man's knowledge of Nature.

P. L.

PROF. RUCKER'S PRESIDENTIAL ADDRESS TO SECTION A.

It is impossible for a body of English scientific men to meet in one of our ancient university towns without contrasting the old ideal of the pursuit of learning for its own sake with the modern conception of the organisation of science as part of a pushing business concern.

We are, as a nation, convinced that education is essential to national success. Our modern universities are within earshot of the whirr of the cotton mill or the roar of Piccadilly. Oxford and Cambridge themselves are not content to be centres of attraction to which scholars gravitate. They have devised schemes by which their influence is directly exerted on every market town and almost on every village in the country. University extension is but a part of the extraordinary multiplication of the machinery of education which is going on all around us. The British Association, which was once regarded as bringing light into dark places, is now welcomed in every large provincial town by a group of well-known men of science; and we find ready for the meetings of our sections not only the chapels and concert-rooms which have so often and so kindly been placed at our disposal, but all the appliances of well-designed lecture-rooms and laboratories.

I do not propose, however, to detain you this morning with a discourse on the spread of scientific education; but you will forgive me if I illustrate its progress by two facts, not perhaps the most striking which could be selected, but especially appropriate to our place of meeting. It is little more than thirty years since the two branches of science with which our Section deals, Mathematics and Physics, have been generally recognised as wide enough to require more than one teacher to cope with them in an educational institution of high pretensions and achievement. In 1860 the authorities of the Owens College, Manchester, debated whether it was desirable to create a Professorship of Natural Philosophy in addition to, and independent of, the Chair of Mathematics. It was thought necessary to obtain external support for the opinions of those who advocated this step. An appeal was made to Profs. De Morgan and Stokes. The former reported that a "course of experimental physics is in itself desirable;" the latter, that "there would be work enough in a large institution for a mathematician and a physicist."

In the end the Chair of Natural Philosophy was established, and the fact that our host of to-day, Prof. Clifton, was its first occupant reminds us how little we have advanced in time and how far in educational development from the days when propositions such as those I have cited were only accepted on the authority of the names of Stokes and De Morgan.

The other fact to which I would refer is that the Clarendon Laboratory, in which the meetings of Section A are to be held, though erected barely a quarter of a century ago, was the first laboratory in this country which was specially built and designed for the study of experimental physics. It has served as a type. Clerk Maxwell visited it while planning the Cavendish Laboratory, and traces of Prof. Clifton's designs can be detected in several of our university colleges.

But though our surroundings remind us of the improvement which has been effected in the equipment of our science, it would not be difficult to indicate weak points which should forthwith be strengthened. On these, in so far as they affect education, I will not dwell—and that for two reasons. In the first place, we meet to-day not as teachers, but as students; and, secondly, I think that whereas we have as a nation awoke—though late in the day—to the importance of education, we are not yet fully awake to the importance of learning. Our attitude in such matters was exactly expressed by one of the most eminent of the witnesses who gave evidence before the "Gresham Commission." In his opinion the advancement of knowledge must in a university in London be secondary to the higher instruction of the youth of London. If this be so—and I will not now dispute it—we shall surely all agree that somewhere or other, in London or out of it, included in our universities or separate from them, there ought to be institutions in which the advancement of knowledge is regarded as of primary and fundamental interest, and not as a mere secondary bye-product thrown off in the course of more important operations.

It is not essential that in such an institution research should be the only task. Investigation may be combined with the routine work of an observatory, with teaching, with the care of standards, or with other similar duties. It is, however, essential that, if the advancement of knowledge is seriously regarded as an end worth attaining, it shall not be relegated to a secondary place.

Time and opportunity must be found for investigation, as time and opportunity are found for other tasks. It is not enough to refer to research in a prospectus, and then to leave it to be accomplished at odd times and in spare moments not claimed by more urgent demands. Those to whom the future of the higher learning in England is dear must plan and scheme to promote the lifelong studies of men, as in the last quarter of a century they have struggled, with marked success, to promote the preparatory studies of boys and girls. That the assignment of a secondary position to research is the more popular view, and that the necessity for encouraging it has as yet hardly been grasped by many of those who control our modern educational movements is, I fear, too true. It is therefore a matter for congratulation that within the last year Oxford has established a research degree, and has thus taken an important step towards gathering within her fold workers of mature years who are able and willing, not merely to gain knowledge, but to add to it.

We may also note, with pleasure and gratitude, that recently the stream of private munificence has been in part directed to the advancement of learning. Sir Henry Thompson has generously offered a sum of £5,000 to provide a large photographic telescope

Digitized by Google

for the National Observatory at Greenwich. The new instrument is to be of 26in. aperture and 22ft. 6in. focal length, or exactly double the linear dimensions of that which has been previously employed. Mr. Ludwig Mond, too, has added to his noble gifts to science by the new research laboratories which he is about to establish in connection with the Royal Institution. Albemarle-street is thronged with memories of great discoveries. The researches of Lord Rayleigh and the remarkable results of Prof. Dewar's studies of matter at low temperatures are maintaining the great reputation which the Royal Institution has gained in the past, and all English physicists will rejoice that prospects of new and extended usefulness are opening before it.

Another hopeful, though very embarrassing, fact is that the increase in the number of scientific workers makes it increasingly difficult to find the funds which are necessary for the publication of their work. Up to the present the author of a Paper has had to submit it to criticism, but when it has been approved by competent judges, it has been published without ado and without expense to himself. This is as it should be. It is right that due care should be exercised to prune away all unnecessary matter, to reduce as far as may be the necessary cost. It will, however, be a great misfortune if judgment as to what curtailment is necessary is in future passed, not with the object of removing what is really superfluous, but in obedience to the iron rule of poverty. Apart from all other disadvantages, such a course would add to the barriers which are dividing the students of different sciences. A few lines and a rough diagram may suffice to show to experts what has been attempted and what achieved, but there is no Paper so difficult to master as that which assumes that the reader starts from the point of vantage which months or years of study have enabled the author to attain, undue pruning will not make the tree of knowledge more fruitful, and will certainly make it harder to climb.

Connected also with the increase in scientific literature is a growing necessity for the publication of volumes of abstracts, in which the main results of recent investigations are presented in a concentrated form. English chemists have long been supplied with these by the Chemical Society. The Physical Society, though far less wealthy than its elder sister, has determined to undertake a similar task. We are compelled to begin cautiously, but in January next the first number of a monthly pamphlet will be issued containing abstracts of all the Papers which appear in the principal foreign journals of physics. In this venture the society will incur grave responsibilities, and I avail myself of this opportunity to appeal to all English physicists to support us in a work, the scope of which will be rapidly extended if our first efforts succeed.

From this brief glance at what has been or is about to be done to promote the study of physics, I must now turn to the discussion of narrower but more definite problems, and I presume that I shall be most likely to deserve your attention if I select a subject in which I am myself especially interested.

During the last ten years my friend Dr. Thorpe and I have been engaged upon a minute magnetic survey of the United Kingdom. The main conclusions at which we have arrived are about to be published, and I do not propose to recount them now. It is, however, impossible to give so long a time to a single research without having one's attention drawn to a number of points which require further investigation, and I shall perhaps be making the best use of this opportunity if I bring to your notice some matters in the practical and theoretical study of terrestrial magnetism which deserve a fuller consideration than has yet been given to them. In the first place, then, there is little doubt that the instruments at present used for measuring the declination and horizontal force are affected with errors far greater than the error of observation.

We employed four magnetometers by Elliott Brothers, which were frequently compared with the standard instrument at Kew. These measurements proved that the instrumental differences which affect the accuracy of the declination and horizontal force measurements are from five to ten times as great as the error of a single field observation. The dip circle, which two generations ago was so untrustworthy, is, in our experience, the most satisfactory of the absolute instruments. In most cases these comparisons extended over several days; but the Astronomer Royal has described, in his recent report, observations made at Greenwich for two years and a-half with two horizontal force instruments. These differ between themselves, and the discrepancy is of the same order of magnitude as those we have detected. If such differences exist between instruments of the Kew pattern, it is probable that they will be still greater when the magnetometers under investigation are of different types. This point has been investigated by Dr. Van Rijckevorsel, who five years ago visited Kew, Parc St. Maur, Wilhelmshaven, and Utrecht, and using his own instruments at each place, compared the values of the magnetic elements determined by himself with those deduced from the self-registering apparatus of the observatory. The discrepancies between the so-called standards, which were thus brought to light, were quite startling, and prove the necessity for an investigation as to their causes.

Magneticians had long been aware that the instruments used by travellers should be compared at the beginning and end of a journey with those at some fixed observatory, to make sure that the comparatively rough usage to which they are subjected has not affected their indications. But Dr. Van Rijckevorsel's expedition first drew general attention to the fact that there are serious differences between the standard observatory instruments themselves. The importance of a careful comparison between them was at once recognised. The Magnetic Sub-Committee of the International Meteorological Conference, held at Munich in the autumn of 1891, resolved that it is "necessary that the instruments employed for absolute measurements at the different observatories should be compared with each other and the results published." As far as I am aware nothing has been done to give effect to this resolution, but the necessity for such an international comparison is urgent. The last few years have been a period of unexampled activity in the conduct of local magnetic surveys. To cite instances from the north-west of Europe only, observations have recently been made on a more or less extended scale in the United Kingdom, France, Holland, North Germany, and Denmark. It will be absurd if these surveys cannot be collated and welded into a homogeneous whole, because we are in doubt whether the indications of our standard instruments for the measurement of declination and dip differ by five or six minutes of arc. If, however, an official international comparison of the magnetic standards in use in different countries is instituted it is probable that only one observatory in each country will take part in it.

It may fairly be left to each nation to determine for itself the relations between the results of measurements made in its own institutions. Apart, therefore, from all other reasons, we in England would only be able to make the best use of an international comparison if we had beforehand set our own house in order, and were able at once to extend the results of experiments made at Kew or Greenwich to Stonyhurst, Valentia, and Falmouth. This we are not at the present moment in a position to do. As far as I know, nobody has ever carried a magnetometer backwards and forwards between Kew and Greenwich to test the concordance of the published results. During the recent survey single or double sets of observations have been made at Stonyhurst, Falmouth, and Valentia, with instruments which have been compared with Kew; but these measurements, though amply sufficient for the purposes of our research, were not numerous enough to serve as a firm basis for determining the discrepancies between the various standards, so that the exact relations between these important sets of apparatus are still unknown.

The first point, therefore, to which I wish to draw the attention of the Section is the necessity for a full primary comparison between the standard magnetic instruments in use at our different observatories. But, if this were satisfactorily accomplished, the question would arise as to whether it should be repeated at regular intervals. We have at present only a presumption in favour of the view that the standards which we know are discordant are nevertheless constant. A single instance may suffice to show how necessary it may be—at all events in the case of outlying and isolated observatories—to put this belief to the test.

In the most recent account of the work of the observatory of the Bombay Government at Colába the dips are discussed for the period of twenty years between 1872 and 1892. During this interval the adjustment of the agate plates upon which the dip needle rolls has thrice been modified. In 1877 the plates were renewed. In 1881 and 1887 the dip circle was taken to pieces and rebuilt. In the intervals the dip, as determined by several needles, but always with this circle, remained approximately constant; but after each overhauling it suddenly altered, increasing by 12′ on the first occasion, by 23′ on the second, and by 20′ on the third. Mr. Chambers states that he "can give no satisfactory account of this behaviour of the instrument," but suggests that "the needle gradually hollows out a depression in the agate plates on which it rolls, and that this characteristic of the dip circle" has not before been discovered owing to the reluctance of magnetic observers to interfere with the adjustments of instruments which are apparently working well.

I do not think this explanation will suffice. Dr. Thorpe and I employed a new dip circle in the earliest part of our survey work, which has remained in accord with Kew for 10 years. During that time the dip has been measured some 700 times with it. This corresponds, I believe, to more than the amount of work done with the circle at Colába in six years, which, in turn, is longer than some of the intervals in which the Colába instruments gave results erroneous to the extent of 20′. I feel, therefore, quite sure that the difficulties which have been experienced at Bombay are not due to any "characteristic [defect] of the dip circle." But, whatever the cause may have been, surely the lesson is that, if such things can happen in so well-known an institution, it is desirable that we should take the moderate pains required to assure ourselves whether smaller—but, possibly, not unimportant—errors are gradually affecting the results at any of our observatories.

Digitized by Google

This brings me to my next point, namely, that if we are to draw conclusions from the minor differences between measurements of secular or diurnal change made in the observatories, it is not only necessary that we should know whether the instruments are strictly comparable and constant, but the observations must be reduced by precisely the same methods. In 1886 the late Mr. Whipple drew the attention of the British Association to the fact that there was a systematic difference between the diurnal ranges of declination at Greenwich and Kew. His results were based on the three years 1870-72. In 1890 two of my students, Messrs. Robson and S. W. J. Smith, extended the comparison to three more recent years (1883-6-7), and obtained results in complete accord with those of Mr. Whipple. It is well known that the average daily oscillation of the magnet is affected by the magnetic weather. Sabine showed that magnetic storms do not merely buffet the needle now in this direction and now in that—they affect its average behaviour, so that the mean swing east and west is different according as we deduce it only from days of magnetic calm, or include those of storm.

Mr. Whipple reduced the Kew observations by two methods,* one of which depended on the calmest days only, while the other included those which were moderately disturbed. Neither agreed exactly with the method in use at Greenwich, but the difference between the results deduced from them was so small when compared with the difference between either and that obtained at Greenwich, that it seemed possible that the diurnal variations, even at these closely neighbouring places, might differ appreciably. The question whether this is so has now been answered. In 1890, at the request of the Kew Committee, the Astronomer Royal undertook to select early in each year five quiet days in each of the preceding twelve months. It was also agreed that, whether they adopted other methods or not, the chief English magnetic observatories should determine the diurnal variations from these days alone. The Greenwich† and Kew observations for 1880 have, therefore, been worked up in exactly the same way, with the result that the discrepancy, which had persisted for 20 years, has entirely disappeared, and that the two diurnal ranges at the two observatories are in as close accord as could be expected. If, therefore, we may judge from a single year, the cause of the difference lay in the choice of days. Greenwich will in future give us two diurnal variations—one obtained from the most quiet days only, the other from all days except those of violent storm, and in these we shall have most valuable data for studying the mean effect of disturbances on the diurnal variation.

To this satisfactory conclusion I have only one suggestion to add. The Astronomer Royal and M. Mascart now publish for the same stormy days the photographic traces by which the history of a magnetic storm is mapped. Is it possible for Greenwich and Paris also to agree in their choice of calm days for the calculation of the diurnal variation, so that a precise similarity of method may obtain not only between the English observatories, but between England and France?

The importance of co-operation between institutions engaged on the same tasks having been illustrated, I am glad to be able to announce that another step is about to be taken in the same direction. For some years, in spite, I believe, of great financial difficulties, the Cornwall Royal Polytechnic Society has maintained a magnetic observatory at Falmouth. The results of the observations have hitherto been printed in the *Journal* of the Society only, but the Royal Society has now consented to publish them in the *Proceedings*. Before long, therefore, the Kew and Falmouth records, which are already worked up in the same way, will be given to the world side by side. Is it too much to hope that this may be the first step towards the production of a "British Magnetic Year Book," in which observations whose chief interest lies in their comparison may be so published as to be easily compared?

We owe to private enterprise another advance of the same kind. The managers of the new journal *Science Progress* have made arrangements with the Kew Committee for the yearly publication of a table showing the mean annual values of the magnetic elements as determined at the various magnetic observatories of the world. It will, therefore, in future be possible to get a general idea of the rate of secular change in different localities without searching through a number of reports in different languages, which can only be consulted in the rooms of the few societies or institutions to which they are annually sent. The present state of our knowledge of the secular change in the magnetic elements affords, indeed, very strong support to the arguments I have already adduced in favour of a comparison between the instruments of our magnetic observatories.

The whole question of the cause of this phenomem has entered on a new stage. It has long been recognised that the earth is not a simple magnet, but that there are in each hemisphere one pole or point at which the dip needle is vertical, and two foci of maximum intensity. A comparison of earlier with later magnetic observations led to the conclusion that one or both of the foci in each hemisphere is in motion, and that to this motion—however caused—the secular change in the values of the magnetic elements is due. Thus the late Prof. Balfour Stewart, writing in 1883, says: "While there is no well-established evidence to show that either the pole of verticity or the centre of force to the North of America has perceptibly changed its place, there is, on the other hand, very strong evidence to show that we have a change of place on the part of the Siberian focus."* The facts in favour of this conclusion are there discussed. The arguments are based, not on the results of any actual observations near to the focus in question, but on the behaviour of the magnet at points far distant from it in Europe and Asia. The westerly march of the declination needle, which lasted in England up to 1818, and the easterly movement which has since replaced it, are connected with a supposed easterly motion of the Siberian focus, which, it is added, "there is some reason to believe . . . . has recently been reversed." In opposition, therefore, to the idea of the rotation of a magnetic focus round the geographical poles, which the earlier magneticians adopted, Stewart seems to have regarded the motion of the Siberian focus as oscillatory.

A very different aspect is put upon the matter by a comparison of the magnetic maps of the world prepared by Sabine and Creak for the epochs of 1840 and 1880 respectively. Capt. Creak, having undertaken to report on the magnetic observations made during the voyage of the "Challenger," supplemented them with the unrivalled wealth of recorded facts at the disposal of the Hydrographic Department of the Admiralty. He was thus able, by a comparison with Sabine's map, to trace the general course of the secular changes all over the world for 40 years. The negative results may be shortly stated. There is no evidence of any motion either of magnetic pole or focus. The positive conclusions are still more curious. There are certain lines on the surface of the earth towards which in the interval under consideration the north pole of the needle was attracted. From each side the compass veered or backed towards them. Above them the north pole of dip needle moved steadily down. There are other lines from which, as tested by compass and dip circle, a north pole was in like manner repelled. The two principal points of increasing attraction are in China and near Cape Horn; the chief points of growing repulsion are in the North of Canada and the Gulf of Guinea. I am sure that my friend Captain Creak would be the first to urge that we should not generalise too hastily from this mode of presenting the facts, but there can be no doubt that they cannot be explained by any simple theory of a rotating or oscillating pair of poles. *Primâ facie* they suggest that the secular change is due not so much to changes at the principal magnetic points, as to the waxing and waning of the forces apparently exerted by secondary lines or points of attraction or repulsion.

All down the west coast of America, close—be it noted—to one of the great lines of volcanic activity, north hemisphere magnetism has since 1840 been growing in relative importance. Near Cape Horn a weak embryonic pole is developing of the same kind as the well-known pole at the other end of the continent near Hudson's Bay. Along a line which joins Newfoundland to the Cape of Good Hope precisely the reverse effects have been experienced, while in the Gulf of Guinea a south hemisphere pole is growing within the tropics. Of course I do not suggest that these secondary systems can ever determine the principal phenomena of terrestrial magnetism, or reverse the magnetic states of the hemispheres in which they occur. These are no doubt fixed by the rotation of the earth. I do, however, wish to emphasise the fact that they show that either secular change is due to the conjoint action of local causes, or that if some single agent, such as a current system within the earth, or a change of magnetic conditions outside it, be the primary cause, the effects of this cause are modified and complicated by local peculiarities.

Mr. Henry Wilde has succeeded in representing with approximate accuracy the secular change at many points on the surface of the earth by placing two systems of currents within a globe, and imparting to the axis of one of them a motion of rotation about the polar axis of the earth. But he has had to supplement this comparatively simple arrangement by local features. He has coated the seas with thin sheet-iron. The ratio between the two currents which serves to depict the secular change near the meridian of Greenwich fails in the West Indies. Thus this ingenious attempt to imitate the secular change by a simple rotation of the magnetic pole supports the view that local peculiarities play a powerful part in modifying the action of a simple first cause, if such exist. I need hardly say that I think the proper attitude of mind on this difficult subject is that of suspended judgment; but there is no doubt that recent investigation has, at all events, definitely raised the question how far secular change

* Sabine's and Wild's.

† The Greenwich observations for subsequent years have not yet been published.

* *Encyclopædia Brit.*, 9th edition. Art. "Meteorology, Terrestrial Magnetism."

Digitized by Google

is either due to or modified by special magnetic features of different parts of the earth.

It is possible that light may be thrown upon this point by observations on a smaller scale. Assuming for the moment that the difference in the secular changes on opposite sides of the Atlantic is due to a difference of local causes, it is conceivable that similar causes, though less powerful and acting through smaller ranges, might produce similar, though less obvious, differences between places only a few miles apart. For testing this Greenwich and Kew are in many respects most favourably situated. Nowhere else are two first-class observatories so near together. Differences in the methods of publishing the results have made it somewhat difficult to compare them, but the late Mr. Whipple furnished me with figures for several years which made comparison easy. Without entering into details, it may be sufficient to say that the declination needles at the two places do not from year to year run parallel courses. Between 1880-82 Kew outstripped its rival, between 1885 and 1889 it lost, so that the gain was rather more than compensated. The difference of the declination of the two places appears to increase and diminish through a range of five minutes of arc.

This evidence can be supplemented by other equally significant examples. No fact connected with terrestrial magnetism is more certain than that at present the rate of secular change of declination in this part of Europe increases as we *go* north. This is shown by a comparison of our survey with those of our predecessors fifty and thirty years ago, by M. Moureaux's results in France, and by Captain Creak's collation of previous observations. Yet, in spite of this, Stonyhurst, which is some 200 miles north of Greenwich and Kew, and should therefore outrun them, sometimes lags behind and then makes up for lost time by prodigious bounds. Between 1882 and 1886 the total secular change of declination at Stonyhurst was about 3'·5 less than that at Greenwich and Kew, whereas in the two years 1890-92 it reached at Stonyhurst the enormous amount of 28', just doubling the corresponding alteration registered in the same time at Kew. If these fluctuations are caused by the instruments or methods of reduction my argument in favour of frequent comparisons and uniform treatment would be much strengthened; but, apart from the inherent improbability of such large differences being due to the methods of observation, the probability of their physical reality is increased by the work of the magnetic survey.

The large number of observations at our disposal has enabled us to calculate the secular change in a new way, by taking the means of observations made about five years apart at numerous though not identical stations scattered over districts about 150 miles square. The result thus obtained should be free from mere local variations; but, as calculated for the south-east of England for the five years 1886-91, it differs by nearly 5' from the change actually observed at Kew.

We have also determined the secular change at 25 stations by double sets of observations made as nearly as possible on the same spot at intervals of several years. The results must be interpreted with caution. In districts such as Scotland, where strong local disturbances are frequent, a change of a few yards in the position of the observer might introduce errors far larger than the fluctuations of secular change. But when all such cases are eliminated, when all allowance is made for the possible inaccuracy of field observations, there are outstanding variations which can hardly be due to anything but a real difference in the rate of change of the magnetic elements. A single example will suffice. St. Leonards and Tunbridge Wells are about 30 miles apart. Both are situated on the Hastings sand formation, and on good non-magnetic observing ground. At them, as at the stations immediately around them—Lewes, Eastbourne, Appledore, Etchingham, Heathfield, and Maidstone—the local disturbing forces are very small. All these places lie within a district about 40 miles square, at no point of which has the magnet been found to deviate by 5' from the true magnetic meridian. No region could be more favourably situated for the determination of the secular change, yet according to our observations the alteration in the declination of St. Leonards in six years was practically equal to that at Tunbridge Wells in five. It is difficult to assign so great a variation to an accumulation of errors, and this is only one amongst several instances of the same kind which might be quoted.

We find, then, when we consider the earth as a whole, grave reason to question the old idea of a secular change caused by a magnetic pole or focus pursuing an orderly orbit around the geographical axis of the earth, or oscillating in some regular period in its neighbourhood. It would, of course, be absurd to admit the possibility of change in the tropics and to deny that possibility in the arctic circle; but the new facts lead us to look upon the earth not as magnetically inert, but as itself—at the equator as well as at the pole—producing or profoundly modifying the influences which give rise to secular change. And then, when we push our inquiry further, accumulating experience tells the same tale. The earth seems, as it were, alive with magnetic forces, be they due to electric currents or to variations in the state of magnetised matter. We need not now consider the sudden jerks which disturb the diurnal sweep of the magnet, which are simultaneous at places far apart, and probably originate in causes outside our globe. But the slower secular change, of which the small part that has been observed has taken centuries to accomplish, is apparently also interfered with by some slower agency, the action of which is confined within narrow limits of space. Between Kew, Greenwich, and Stonyhurst, between St. Leonards and Tunbridge Wells, and, I may add, between Mablethorpe and Lincoln, Enniskillen and Sligo, Charleville and Bantry, the measured differences of secular variation are so large as to suggest that we are dealing not with an unruffled tide of change, which, unaltered by its passage over continent or ocean, sweeps slowly round the earth; but with a current fed by local springs or impeded by local obstacles, furrowed on the surface by billows and eddies, from which the magnetician, if he will but study them, may learn much as to the position and meaning of the deeps and the shallows below. But if this is the view which the facts I have quoted suggest, much remains to be done before it can be finally accepted; and, in the first place—to come back to the point from which I started—we want, for some years, at all events, a systematic and repeated comparison of the standard instruments in use at the different observatories. That they are not in accord is certain; whether the relations between them are constant or variable is doubtful. If constant, the suggestions I have outlined are probably correct; if variable, then the whole or part of the apparent fluctuations of secular change may be nothing more than the irregular shiftings of inconstant standards. I cannot myself believe that this is the true explanation, but in any case it is important that the doubt should be set at rest, and that if the apparent fluctuations of secular change are not merely instrumental, the inquiry as to their cause should be undertaken in good earnest.

The question is interesting from another point of view. It is now fully established that even where the surface soil is non-magnetic, and even where geologists have every reason to believe that it lies upon non-magnetic strata of great thickness, there are clearly-defined lines and centres towards which the north-seeking pole of a magnet is attracted, or from which it is repelled. To the magnetic surveyor fluctuations in secular changes would appear as variations in the positions of these lines, or as changes in the forces in play in their neighbourhood.

Greenwich and Kew are both under the influence of a widespread local disturbance which culminates near Reading. At both places the needle is deviated to the west of the normal magnetic meridian, and if the westerly declination diminishes sometimes faster and sometimes more slowly at one observatory than at the other, this must be, or, at all events, would in the first instance appear to be, due to local changes in the regional disturbing forces. The question of the nature of the variations of secular change and of the causes of local disturbances are therefore intermingled; and information gained on these points may in turn be useful in solving the more difficult problem of world-wide secular variations.

Two causes of regional and local disturbances have been suggested, viz., earth currents, and the presence of visible or concealed magnetic rocks. The two theories are not mutually exclusive. Both causes of the observed effects may, and probably do, coexist. I have, however, elsewhere explained my reasons for believing that the presence of magnetic matter, magnetised by induction in the earth's field, is the principal cause of the existence of the magnetic ridge-lines and foci of attraction which for so many years we have been carefully tracing. I will only now mention what appears to me to be the final and conclusive argument, which, since it was first enunciated, has been strengthened by the results of our more recent work. We find that every great mass of basic rock, by which the needle is affected at considerable distances, attracts the north-seeking pole. Captain Creak some years ago showed that the same statement is true of those islands in the northern hemisphere which disturb the lines of equal declination, while islands in the southern hemisphere repel the north pole and attract the south. In other words, these disturbances are immediately explained if we suppose that they are due to magnetic matter magnetised by induction. The theory of earth currents would, on the other hand, require that round the masses of visible basalt, and round the island investigated by Captain Creak, currents, or eddies in currents, should circulate in directions which are always the same in the same hemisphere, and always opposed on opposite sides of the equator. For this supposition no satisfactory explanation is forthcoming, and therefore, with all reserves and a full consciousness that in such matters hypothesis differs but little from speculation, it appears to me that the theory of induced rock magnetism, as the main cause of the disturbance, has the greater weight of evidence in its favour.

If this be granted, it is evident that the positions of the main lines and centres of attraction would be approximately constant, and, so far as it is possible to form an opinion, these conditions seem to be satisfied. There has certainly been no noticeable change in the chief loci of attraction in the five years which have elapsed
